# CANADIAN MACHINERY

## AND MANUFACTURING NEWS

A weekly newspaper devoted to the machinery and manufacturing interests.

Vol. XVI.

TORONTO, JULY 6, 1916

No. 1

### EDITORIAL CONTENTS

The Dominion of Canada Celebrates its Fiftieth Birthday .....	14
General .....	4
Packing of Machinery, Hardware, etc....Hints for Trade Extension Abroad....C.P.R. Resources Expert on Preliminary Investigation.	
Plant and Product of the Bawden Machine Co., Toronto .....	5-8
General .....	8
Ships' Option—Weight or Measurement.	
Ocean Terminal and Port Development at Halifax, N.S. ....	9-13
General .....	13-14
Prospects for Trade in Russia....The Shipping Outlook....Good Packing Essential.... Canadian Car & Foundry Munitions Shipments.	
United Shoe Machinery and United Last Co. Plants .....	15-19
Editorial .....	20
World-Wide Progress Following the War....Factors in Our Munitions Production.	
Industrial Notabilities .....	21
Thomas Joseph Dillon.	
Selected Market Quotations .....	22-24
The General Market Conditions and Tendencies .....	24-27
Montreal Letter....Toronto Letter....Shipping Facilities for Export Trade....Agricul- tural Machinery Needed in India.	
Industrial and Construction News .....	28

### THE MACLEAN PUBLISHING COMPANY, LIMITED

JOHN BAYNE MACLEAN, President.

H. T. HUNTER, Vice-president.

H. V. TYRRELL, General Manager

Publishers of Hardware and Metal, The Financial Post, MacLean's Magazine, Farmer's Magazine, Canadian Grocer, Dry Goods Review, Men's Wear Review, Printer and Publisher, Bookseller and Stationer, Canadian Machinery and Manufacturing News, The Power House, The Sanitary Engineer, Canadian Foundryman, Marine Engineering of Canada.

Cable Address: Macpubco, Toronto; Atabek, London, Eng.

ESTABLISHED 1887.

# Hendey Millers will take any kind of a miller job

*that comes into the modern shop*

and it delivers the finished work in the highest degree of accuracy and perfection. It has a wide range of spindle speeds (16) and feeds (18).

The "Hendey" is free from the usual complicated features. All working positions are secured with but few and easily understood movements on the part of the operator. Anyone can operate the "Hendey Miller." No special skill is required to get the service that the Hendey's built for.

Write for the "Hendey Miller" Book. It is certain to interest you.

**The Hendey Machine Co.**  
Torrington, Conn., U.S.A.

Canadian Agents: A. R. Williams Machinery Co., Toronto, Ont.; A. R. Williams Machinery Co., 260 Princess St., Winnipeg; A. R. Williams Machinery Co., Vancouver; A. R. Williams Machinery Co., St. John, N.B.; Williams & Wilson, Montreal.

## The Dominion of Canada Celebrates Its Fiftieth Birthday

Contributed and Selected

*On this and the immediately succeeding pages, it seems fitting that reference both specific and general be made to the development of Canada's natural resources and to the upbuilding of her industry and commerce. She has just celebrated her fiftieth birthday, and it goes without saying that at no previous or similar epoch has her prosperity been more marked, her enterprise been more demonstrative, and her Empire allegiance been more sincere.*

**D**OMINION Day, July 1, 1916, found Canada in many respects more enterprising and progressive than at any time since Confederation. Various reasons may be assigned as being contributory or responsible for the initiation of her new and broadened outlook. The bumper crop of 1915, the meantime satisfactory condition of that of the present year, and the aptness with which our metal-working and manufacturing plants generally have negotiated munitions production, may, however, be reckoned as the chief factors.

### A New Inspiration Evident

Not only has a new inspiration come to us, but coincident with it much of our latent individual and collective ability to observe and perform has been revealed. We have come to realize that not only are we big and strong enough to take care of a larger proportion of our own ever-increasing domestic needs and undertakings, but we can prepare to take a hand in the many business opportunities presently offering abroad; all of which will necessarily increase in number, extent and diversity, as the trade unification plans of our Empire and her Allies develop and mature.

Our record since Confederation is no mean one, as the accompanying data and statistics amply bear out. We have accomplished much in agriculture, mineral reclamation, manufacturing and transportation during the intervening period.

and most gratifying of all, we have contrived to equip our national machine in its myriad intricacies so as to play a relatively important part in the world's future commerce and industry. We have taken cognizance of what other and older countries have found advantageous, and have appropriated their ideas; on the other hand, we have discriminated against many of the disabilities under which they labor. As a result, it requires no stretch of imagination to affirm that, with the lapse of a similar period ahead, our national progress and achievement will be in marked degree accelerated.

It has been during the last quarter century or even less that our greatest development has taken place; its trend and activity were, however, self-contained. In the coming time, and because of the latter, the scope of our activities will become enlarged so as to be world-embracing in their application. This, needless to say, is already abundantly evident in the expressed desire and effort being concentrated towards the distribution of the products of our fields, our mines and our factories in lands hitherto unfamiliar, and in many cases altogether ignorant of our trade and commerce capacity.

### Territorial Area

Canada has one-third of the area of the British Empire, and a majority of the white population of the Empire outside of Great Britain.

Canada is bounded by three oceans; its 13,000 miles of coast line is nearly equal half the circumference of the earth.

Canada is 3,500 by 1,400 miles in area. The United States-Canada boundary line is 3,000 miles long; 1,600 by land, 1,400 through water.

Canada is as large as 30 United Kingdoms and 18 Germanys; twice the size of British India; almost as large as Europe; 18 times the size of France; 33 of Italy.

Canada is larger in area than the United States, including Alaska, by 111,992 square miles (Canada, 3,729,665; United States and Alaska, 3,617,673).

In 1868, area of the four provinces forming Confederation was 662,148 square miles; now Parliament exercises jurisdiction over 3,729,665 square miles in nine provinces.

### Land of Opportunity

Our Prime Minister, Sir Robert L. Borden, says that Canada without any booming is going to be one of the greatest countries in the world, even if England neither sent a man nor a penny piece out there.

"The Canada of to-day is a land of peace and plenty, a place of sunshine and big crops, a country whose soil spells wheat, and out of whose farms thousands are growing rich.

"Canadians have reason to feel proud of the laws governing the country and

the manner in which they are administered. There is an observance of established authority that is appreciated by all law-abiding citizens.

"In religious matters and politically Canada is the freest country in the world. There is no established religion, and each person is at liberty to worship as he pleases.

"Each province is in absolute control of its own system of education, and probably no country in the world enjoys a broader or more generous system.

"Do you realize how great a country Canada is? If you could pivot Canada upon its eastern seaboard, it would cover the northern part of the Atlantic Ocean, the British Islands, Norway, Sweden, Denmark, Holland, Belgium, the northern part of France, the entire German Empire, and a considerable part of European Russia, and a man who lives in Halifax is a thousand miles farther away from Victoria than he is from London."

### Agriculture

Canada's harvest for 1915 was the most bountiful in her history, making new records for quantity, quality, and value.

Canada's total grain crop of 1915 was a record-breaker, totalling 10,194,609,250 bushels, worth \$800,000,000, and this from less than 10 per cent. of the arable area. This was Canada's record-breaker both in field crops value and production.

Canada's total tilled area in 1915 was 37,263,000 acres; in 1914, 33,440,075.

Canada is increasingly becoming the great granary of the Empire.

Canada's wheat yield for 1915 was 376,303,600 bushels, worth \$312,569,400, or 215,023,600 bushels more than in 1914. Average yield per acre, 28.98 bushels; 1914, 15.67.

Canada has 543 flour mills, with a daily capacity of 111,865 barrels.

Canada's exportable wheat and flour, from the 1915 harvest, is estimated at \$200,000,000.

Oats were Canada's greatest crop; 520,103,000 bushels in 1915; worth \$170,894,700. Yield in 1914, 313,087,000 bushels.

Other principal crops: Barley, 53,331,300 bushels, worth \$26,704,700; rye, 2,394,100 bushels, worth \$1,899,900; peas, 3,478,850 bushels, worth \$5,730,700; root and fodder crops value, \$229,623,000.

Canada's total dairy production totalled (census of 1910), \$109,339,934. Dairy product exports, 1914-15, \$22,952,560, mostly cheese.

Canada had in 1915, 14,212,662 head of live stock.

Canada's cattle value increase in ten years, 1901-1911, was \$24,755,000, or 14 per cent.

Canada's horse value increase in ten

years, 1901-1911, was \$260,607,000, or 200 per cent.

### Population

Canada's population:—1867, 3,371,594; 1911, 7,206,643, more than double. By the same ratio Canada would have, at the end of the next fifty years, viz., in 1967, or at the conclusion of a century of Confederation, fifteen millions. Canada's present population is estimated at 8,075,000. The last ten-year increase, 1901-1911, was 34 per cent., as against 24 per cent. in the United States for the same period.

Canada's population is about two per square mile; that of the United States about 30. If Canada had the square-mile population of the United States it would have 111,000,000.

Canada had, in 1871, 21 cities and towns of over 5,000 inhabitants; in 1911 there were 90.

"Long before the end of this century Canada will have 75,000,000 people."—Watson Griffin in "Canada the Country of the Twentieth Century."

### Trade Growth

Canada's total foreign trade has jumped from \$131,027,532 in 1867 to \$1,120,253,771 in 1915. Average per head, 1867, \$38.35; 1915, \$137.69. Imports in 1867 were \$73,459,644; in 1915, \$629,444,984. Exports in 1867 were \$57,567,888; in 1915, \$490,808,877.

Canada's trade has expanded from dealing with a few countries to those now numbering seventy.

Canada's trade growth since Confederation has been remarkable.

Canada ranks third in the ratio of her trade per head.

Canada's trade has more than doubled in nine years, and trebled in fourteen; being nine times greater than what it was at Confederation.

### Manufactures

Canada's industrial growth has been in keeping with her great development in other lines; it has been markedly so since 1900.

Canada has more than a billion dollars invested in her factories, which make over 300 different varieties of product.

It is estimated that over 300 United States firms have factories in Canada.

The value of goods made in Canadian factories is estimated at \$1,400,000 a year, based on normal capacity.

### Railroads

Canada's railway mileage, June 30, 1914, 30,795; increase of 1,491 in year. Doubled in 20 years. Mileage in 1836, 16; at Confederation, in 1867, 2,278.

Canada has, on basis of population, the highest ratio of railway mileage of any country in the world, viz., 3.75 miles per head.

Canada has more miles of railway in operation than Australia, New Zealand, Italy, and Spain combined; more than Sweden, Norway, Denmark, Belgium, Holland, Switzerland, and Roumania joined together.

Only four countries now exceed Canada in railway mileage—United States, Russia, Germany, India.

Canada added more than 10,000 miles to her operative railway mileage in the last decade. No other country in the world has equalled it.

Canada's railways have been given cash subsidies of \$228,772,640, viz., \$178,839,528 from Dominion, \$37,023,275 from provinces, and \$17,914,836 from municipalities. Dominion and Provincial Governments have also guaranteed railway bonds for many millions.

Canada's railways employ 159,142. Annual salaries and wages, \$111,762,972.

### Resources Development and Achievement

Canada's canal at Sault Ste. Marie is the greatest single lock in the world. This lock has a length of 1,350 feet, with a width of 50 feet, a height of 50 feet, and a lift of 20 feet. These dimensions surpass those of any other lock in the world, the length of the biggest lock in the Kiel Canal being but 1,082 feet.

Canada has built the largest irrigation dam in America at Bassano, Alta., 7,000 feet long.

Canada is about completing the largest railway tunnel in America, in the Rogers Pass.

Canada is building the largest single span bridge in the world, at Quebec.

Canada is building a new \$60,000,000 Welland Canal.

Canada is spending many millions on great harbor works in Halifax and St. John, and in deepening the St. Lawrence ship-channel.

Canada is erecting the largest telescope in America, on Vancouver Island.

The Canadian Government has built five large grain elevators.

Canada has the largest grain mills in the British Empire.

Canada has the world's largest lift-lock, at Peterboro.

Canada has the largest buffalo herd left on the continent, between one and two thousand.

Canada has the largest and richest nickel mines in the world.

Canada will have the longest bridge span in the world, at Quebec.

Montreal harbor has the largest grain conveying system in the world.

Canada has the most prolific and extensive sea fisheries in the world.

Ontario's Hydro-Electric Power transmission line is the longest in the world.

Canada possesses the largest pulp-wood resources of any country in the world.

Canada has the largest consecutive

wheat field in the world, 900 by 300 miles.

Canada has one of the highest tides in the world—59½ feet—in Noel Bay, Bay of Fundy.

The thickest known coal seam in the world—47 feet—is at Stellarton, Nova Scotia.

Canada has the largest elevator in the world at Port Arthur; capacity, nearly ten million bushels.

Toronto's Industrial Exhibition is the largest annual fair in the world.

### Water Powers

One of Canada's richest assets is in her water powers, which have only been developed since Confederation. Canada's estimated water power is 16,600,000 h.p., equal to an annual production of 367,000,000 tons of coal. Only a little over 1,000,000 h.p. thus far developed. Canada possesses, it is claimed, a larger amount of potential water power than any other country.

### Irrigation

Irrigation methods were practically non-existent in Canada at several large irrigation systems in Confederation. To-day there are Alberta and British Columbia. The C. P. R. project will irrigate part of a tract of 3,000,000 acres of land east of Calgary, involving 2,500 miles of canals and ditches.

### Shipping and Shipbuilding

Canada's marine progress has been steady. Her net registered vessel tonnage, December 31, 1914, was valued at \$27,972,660.

Canada now occupies the tenth place among maritime nations. Registered vessels, December 31, 1914, 8,772, measuring 932,422 net tons, employing 45,168 men and boys; 327 vessels valued at \$1,950,570 added to list in 1914; 212 removed from register.

Tonnage of vessels built in Canada, 1914-15, 45,721; doubled in five years. Tonnage of vessels registered, 55,384.

Canada's sea-going, coasting, and inland shipping, inwards and outwards, fiscal year 1914-15, 259,192 (275,139 in 1913-14); aggregate tonnage, 126,704,135.

### Finances

Canada's Government revenue, first year of Confederation, \$13,687,928; 1915-16, \$170,000,000.

National public debt, 1867-68, \$96,846,666; March 31, 1916, \$580,000,000.

Canadian people's savings on August 30, 1915, in the chartered banks, post offices, and other institutions authorized by the Government to accept deposits,

amounted to \$1,134,367,051, or \$140 per head of 8,000,000 population.

"Round Table" estimate of Canada's capital wealth, \$9,920,000,000.

The position of the chartered banks of Canada is stronger than in any other period since Confederation.

### Western Canada

Western Canada's development has almost entirely come since Confederation.

Western Canada has nearly 3,000 elevators, with a capacity of nearly 100,000,000 bushels.

The three Prairie Provinces are three times the area of the German Empire.

Less than 10 per cent. of Western Canada's arable area is under cultivation at the present time.

Illustration courtesy Engineering Review.

The three North-West Provinces' estimated yield of wheat in 1915 was 304,200,000 bushels, out of 336,258,000, or 90 per cent.; oats, 305,680,000 bushels, out of 481,035,000, or 63 per cent.

The Peace River country, the Last Great West to be opened up, has 45,000,000 acres of arable land—"a new kingdom of arable richness."

Practically all of the Western cities have come into existence since Confederation.

### Banks

In no department has Canada's development since Confederation been more strikingly shown than in that of banking. Canada's paid-up bank capital in 1888 of \$30,507,447 increased to \$115,984,389 in 1915; bank deposits from

\$33,653,594 to \$1,123,673,735; assets from \$77,872,257 to \$1,574,210,941, and post office deposits from \$1,687,808 to \$39,995,406.

### Canada's Part in the War

Canada is fully determined to spare no effort and shrink from no sacrifice to make triumphant the cause of the Allies, says Sir Robert L. Borden.

Dominion Day, 1916, finds Canada in the world's greatest war, with a national and an Empire unity never before known.

Canada has pledged 500,000 men to Great Britain and the Allies. Of this number, 350,000 have enlisted, and additional enlistments are averaging a thousand a day.

Canada's war expenditure thus far (through the Federal Government and Parliament) totals \$400,000,000, including Government war vote for current year of \$250,000,000.

Over 400 industrial plants are making shells and other munitions.

Canada has given \$10,000,000 for its Patriotic Fund, and as many millions for Red Cross and similar purposes.

The first Canadian contingent of nearly 33,000 men, 7,500 horses, and 70 pieces of artillery, was the largest military force that ever crossed the Atlantic.

Canada was supporting in the fall of 1915, 10,000 beds in France, England, etc., distributed between 16 hospitals, with staffs of over 2,000 doctors and over 500 nurses.

### Immigration

Government encouraged and regulated immigration, practically unknown at Confederation, started in 1907. Total arrivals since then, 3,172,865, viz., 1,197,995 British, 1,090,457 United States, 882,423 foreign, representing 43 nationalities.

Japanese immigration, 1907-1915, 11,741; Chinese, 28,725.

Canada's foreign population was 6 per cent. in 1901; 11 per cent. in 1911.

### Labor Unions

Labor unions were practically non-existent in Canada at Confederation. Now there are over 2,000 local trade union branches, with 166,163 members, according to returns at end of 1914.

### Fisheries

Canada has the most extensive and best stocked commercial fishing waters in the world, including 5,000 miles of Atlantic and 7,000 miles of Pacific coast, and 220,000 square miles of fresh water. Canada's fishery exports have increased from \$3,357,510 in 1867 to \$19,687,086 in 1914-15.

### Mineral Wealth

Canada possesses practically every known mineral.

Canada's total mineral production since Confederation, \$1,645,608,421.

Production value, 1886, \$10,221,255; 1914, \$128,475,499. It has doubled in the last ten years.

Canada's mineral exports were only \$1,267,129 in 1867; \$53,781,102 in 1914.

Canada produces 80 per cent. of the world's nickel output. Production in 1914, 45,517,937 pounds, worth \$13,655,381.

Cobalt silver production since 1909, \$113,751,261.

### Canals

Canada has a remarkable canal system in comparison with its vast area and relatively small population, viz., 100 miles (linking together 1,594 miles of waterways), at a cost of over \$100,000,000. The traffic through the Canadian canals on Canadian vessels jumped from a tonnage of 2,681,639 in 1885 to 12,050,856 in 1914, and on United States vessels from a tonnage of 547,438 in 1900 to 15,636,414. Freight carried, 1885, 3,673,641 tons; 1914, 37,023,237 tons.

### Customs Revenue

Canada's chief source of revenue. Customs duties, has increased from \$8,801,446 in 1867 to \$104,691,238 in 1915, and excise from \$3,002,588 to \$21,452,037.

### Telephones and Wireless

The telephone has come into existence since Confederation, and to-day Canada is one of the world's greatest telephone users, there being one for every 15 of population.

Canada had, in 1914, over half a million telephones and 1,136 telephone organizations.

Canada is the home of the telephone, being first used in Brantford, "the Telephone City."

Wireless is also new since Confederation. Canada has a chain of wireless stations, making one of the best marine telegraph services in the world.

### Mails and Parcels

The post offices of a country are a measure of its growth. Canada's expansion in this regard has been striking, from 3,638 at Confederation to 13,348 on March 31, 1915.

Letters mailed in 1868 amounted to only 18 millions; in 1914-15 they were 684,000,000.

Parcel post and rural mail deliveries are new features.—Toronto Star abstract.

### PACKING OF MACHINERY, HARDWARE, ETC.

TO facilitate easy handling and minimize chances of breakage, cases containing machines should be as small as possible, and all parts should be snugly

tight in the case or crate, as the least bit of movement may result in serious damage. Pieces of irregular form should be braced at every curve and angle, the box itself being reinforced inside and out to prevent its going to pieces if suddenly dropped. A very important precaution is the covering of the machinery itself in such a way that if the cases are exposed to rain the contents will not get wet, and it is advisable to cover all metal parts with vaseline or similar substances to prevent rust.

Because of its weight, hardware should be packed in as small compass as practicable, and in cases that will stand rough and frequent handling. Protection against damp should be supplied and close attention paid to the requests and suggestions of buyers, which, it is claimed, are frequently overlooked in these lines. Nails should be packed in strong kegs bound with four or five steel hoops, and have reinforced ends; otherwise there is generally considerable breakage in every shipment, the loss ensuing from pilfering and other causes falling upon the foreign importer or the native dealer who buys from him.

If the shipper wishes the consignee to receive his cargo in satisfactory condition he must pack to protect against dampness, and have the cases stout and iron banded to prevent breaking and to give greater immunity from depredations in warehouses, etc.

### HINTS FOR TRADE EXTENSION ABROAD

AT this time when Canada is making wide preparations for an extension of its foreign trade, the following hints from The Board of Trade Journal may be of interest to such of our manufacturers as may be considering the question of entering a new market:—

When it is remembered that success or failure depends at least as much on the organization of a business campaign as on the intrinsic value of the goods offered when compared with those of competitors, the manufacturer contemplating extending his business in a new market will realize the desirability of himself making a preliminary visit to the district. He will thus be in a position to judge for himself the extent of the business to be done and to prepare an organization which will diminish as far as possible the disadvantage due to his inevitable absence.

The most deliberate care and attention should be given to the choice of a representative. Such a man, besides having a complete knowledge of the language and customs of the locality in which he works, should be a thorough expert in his trade and be able to adapt his knowledge to local requirements. He should not be treated as a mere employee, and above all he should not be paid a fixed

salary only, but his remuneration should be arranged on a commission basis with an adequately generous allowance for expenses. Shipping agents who are British subjects should be chosen wherever possible.

Emphasis is laid on the desirability of commercial travellers being provided with sufficient samples, price lists, catalogues, etc., in the language of the country; on the economy to be obtained by groups of non-competitive manufacturers combining to send one representative; the need to conform to local tastes as to the manner of presentation of the article, packing and labelling, etc.; the need of certain markets for giving long credits; and for quoting inclusive prices—factory to customer's warehouse or shop—for goods.

### C.P.R. RESOURCES EXPERT ON PRELIMINARY INVESTIGATION

GEORGE BURY, vice-president of the C.P.R. left Montreal on June 22, for the West on his regular trip of inspection, accompanied by A. D. Little, whose firm is, under arrangement with Lord Shaughnessy, to examine into Canada's mineral and other unutilized wealth, with a view to making the same productive as respects the general industries of the country as a whole.

Mr. Little will make a general examination of a preliminary nature, at points which offer evidence of metaliferous wealth, but the work of systematizing and classification will follow later on. The firm of Little & Company, are located on McGill, St., Montreal, which will be headquarters for the organization, now getting under way. It will be the business of the firm to analyze values and possibilities, and report same to an Advisory Committee, which will, in turn, report to Lord Shaughnessy.

The effect of the examinations and appraisements are, it is understood, to give to the untouched and unknown (in great part) riches of the country a chance of utilization in connection with native industries and exploitation, so that the country, through the wealth it bears in its bosom, may become self-contained to a greatly increased degree. In a word, Mr. Little will try to reveal, through his investigations, the enormous wealth of the country and it will then be for capitalists to utilize it in the various processes of manufacture, instead of being dependent upon outside aid in the fabrication of such things as we require in our commercial and industrial life. The mineral wealth of the Dominion has it is believed been little more than "scratched," so to speak, and it will take Mr. Little and the staff he has assisting him, a considerable time to make the necessary investigations.

# Plant and Product of the Bawden Machine Co., Ltd., Toronto

## Staff Article

*War-time demands have in many cases been the cause of very complete changes in the output of our factories, and to few firms indeed has the great strife occasioned less complete reversals of activity than the plant described. On the contrary, its services to the country have involved rather an intensification of its previous efforts, which by reason of the personnel, plant and product, have been rendered of increasing value to the country in the present crisis.*

**W**HILE much of the success attendant on Canadian munitions manufacture has been due to the whole-heartedness with which so many firms entered on the work, the fact remains that without the necessary equipment many factories would not today be shipping shells. Despite the immensity of the machine tool production in the States, the demands from other countries greatly restricted the supply of tools from that quarter, and the business acumen of several of our home firms in taking up the manufacture of machine tools, not only minimized the handicap from which shell production suffered, but afforded an opportunity for Canadian machines to firmly establish themselves on the market as a permanent product possessing all the features of advanced design, with the reliability and capacity arising from proper material and thorough workmanship.

### A Machine Building Organization

With an established reputation of eight years' standing, the outbreak of hostilities found the Bawden Machine Co. of Toronto busily engaged in all of the activities connected with general and special machine shop work. As builders

of the Bawden pump, the company was thoroughly au fait with manufacturing methods; at the same time, the accumu-

FIG. 2. VIEW IN ASSEMBLY DEPARTMENT WITH MAIN BAY IN BACKGROUND.

lated experience of many years on special machine building also had a considerable influence on the decision of the

company's officials to confine their war efforts to supplying machines rather than shells, and their measure of success-

siderable additions to present plant, the acquisition of which three years ago was rendered necessary by the increasing extent of the company's business. The quantity production of lathes has necessitated additional floor space, while the regular supply of castings is insured by the Worr Foundry Co., which operates a modern foundry plant in conjunction. A completely equipped pattern shop and smith shop are operated, while the tool room has done excellent work in producing testing and gauging devices in endless variety for the use of shell makers.

### Main Shop Equipment

The brick office building is 50 ft. long, extending across the western end of the main bay, which is 50 ft. wide by 108 ft. long. A view of the main bay looking east is shown in Fig. 1, the machines in the immediate foreground being a Fellows gear shaper and a 12 ft. by 30 in. by 30 in. Whitecomb-Blaisdell planer. A No. 3 Cincinnati plain miller and a 48 in. Colburn boring mill are located beyond the planer. A Universal boring machine is largely occupied on boring and facing pump cylinders and hydraulic press castings.

At the eastern end of the main bay is a cross bay, which includes assembly department, tool room and smiths' shop. Part of the assembly floor is shown in Fig. 2, the large lathes in the background being part of the main bay. Prominent

FIG. 1—INTERIOR OF MAIN BAY LOOKING EAST.

can be readily noted by any observing visitor to our leading munition plants. Increased output has demanded con-

FIG. 3—A 16-IN. LATHE READY FOR SHIPMENT.

among the lathes are a 42 in. Bradford, triple geared, a 48 in. New Haven, a 30 in. Bertram, and a 48 in. triple geared facing lathe, with two tool rests on cross slide.

Other representative tools are a No. 4 Cincinnati vertical miller, a 36 in. Gisholt vertical turret lathe, and a No. 3 Becker universal miller; while the drill department includes two 36 in. Fosdick radials, one 36 in. Cincinnati-Bickford

radial, and one 12 in. Rockford vertical drill press. The portion of the assembly floor shown in Fig. 2 is served by a 5-ton Herbert Morris travelling chain hoist, hand operated.

The process of assembling when completed in this part of the works finds the lathe in close proximity to the shipping door, Fig. 3 being taken from the door and showing a completed lathe suspended from the crane.

### Special Purpose Machines A Feature of the Shop Product

The manufacture of machinery for special purposes has always been a feature of this firm. Cloth dryers, gasoline engines, hydraulic presses and automatic machinery for numerous purposes indicate the wide field of application to which the firm's activities have been directed, some of the more specialized apparatus consisting of machines for making corrugated bottle caps, stereotype machines, and automatic machinery for producing twist drills.

Reference has already been made to the tool room. In the case of repetition work, the importance of tool room facilities as a factor in successful production is thoroughly recognized, but in special machinery building the necessity of a tool room is not always so evident, especially when a high grade of work is constantly in progress and the standard of excellence is uniformly high throughout the plant. In the case of this plant, the tool room might well be termed the light machine shop, as owing to the nature of its equipment it is capable of turning out a large variety of work in addition to performing the regular work of tool upkeep, etc.

### Tool Room Equipment

Two views of this department are shown in Figs. 4 and 5, while some of its more recent products are shown in Fig. 6. Here, as throughout the remainder of the plant, careful discrimination has been shown in selecting the equipment.

FIG 4—GENERAL VIEW OF TOOL ROOM.

The lathes include two 18 in. Reed; one 18 in. Lodge & Shipley; and one 18 in. Hendey, all of the tool room type, with full equipment. In Fig. 6 can be observed a No. 3 Modern grinder, and beyond this is a 36 in. Le Blond heavy duty turret lathe. A No. 4 Landis grinder and one Stevens tool grinder complete the machines of this type; while the milling machines include one No. 3 Becker vertical mill and a No. 2 Cincinnati. Minor, but none the less useful items, are a Thomson metal band saw and a Hartford bench filing machine.

#### Interesting Gauge Work

For many months the tool room has been almost entirely devoted to the making of gauges and testing machines for use by the officials of various Governments and private munitions makers.

FIG. 6. GROUP OF GAGES FOR VARIOUS SIZES OF SHELLS.

With the gradual increase in size of projectiles produced in this country the types of gauges have undergone slight alteration. The samples shown in Fig. 6 are but a small variety of the work done in this respect. To the right of the picture is a partly finished cylindrical gauge for 8 in. shells. Lying on the floor beside it is a plug gauge for 18-pdr. fixed ammunition, and toward the left of that is a replica of a gun chamber for gauging finished cartridge cases. The gauge in the centre is for testing the cylindricity of shell bodies, the vertical arm carrying an indicator which shows variations in thousandths of an inch from a true circle. The gauges hanging up behind include one ring and one snap gauge, and four special caliper gauges for testing the wall and base thickness of large shells.

#### Smith Shop and Hardening Department

Adjacent to the tool room is the smith

FIG. 5. VIEW IN TOOL ROOM SHOWING GRINDING.

shop, which is equipped with three hearths, three gas-fired hardening furnaces, one brazing hearth, and one 8½ lb. Dupont power hammer, built by the Plessisville Foundry Co. All products of combustion from the hardening furnaces are taken care of by a special ventilating system, and every precaution has been taken to insure the safety and comfort of the workers in this department.

A view of the pattern shop is reproduced in Fig. 8, from which an idea of the equipment

may be gained. Included are one Crescent band saw; one C. M. C. disc and wheel sander; one American saw bench, surfacer, and planer, and the usual lathes and smaller equipment, all being operated by a 25 horse-power Canadian Westinghouse motor.

The provision of this department has been rendered doubly necessary by reason of present industrial conditions and the extent of the firm's activities, which make quick delivery and perfect accuracy of patterns a desideratum in work of the nature usually undertaken by the company. In accordance with modern practice, the pattern shop is located within convenient access of the drafting room, and is adjacent to and on the same level as a gallery which extends along one side of the main bay, forming accommodation for brassfinishing and special manufacturing, experimental work, etc. This gallery is twenty feet wide, and has a liberal equipment of lathes, drill presses, millers, etc.

FIG. 7. SMITH SHOP SHOWING HARDENING FURNACES AND POWER HAMMER.

### Foundry

The foundry, which as already mentioned is operated as a separate concern, makes a special feature of gray iron castings up to seven tons in weight, the capacity at present being approxima-

Every facility has been provided to insure a continued high grade of product. Tungsten lamps are liberally used throughout offices, factory and foundry. Excellent wash room accommodation is installed for the men, and ample heating

### SHIP'S OPTION—WEIGHT OR MEASUREMENT

WHEN a steamship company makes a freight quotation "per ton, weight or measurement, ship's option," it is understood that the charge will be made on a weight basis if the weight of the shipment exceeds the cubic measurement of same, or on a measurement basis should the cubic measurement exceed the weight, while practically all the foreign steamship lines quote freight rates on the basis of 2,240 pounds or 40 cubic feet measurement to the ton.

Disputes are frequent between shippers and steamship companies in regard to the cubic measurements of packages. Sometimes these are the result of careless measurement on the part of the shipper, but usually the dispute arises because of the fact that steamship companies, as a rule, measure all packages in a rectangular way, so that all those irregularly shaped are estimated as though rectangular and are figured by their greatest dimensions. The reason for this is that irregular packages are not easily stowed, as it may be difficult to find smaller packages to fill in the vacant spaces, in which case "dunnage" or ship's lumber has to be used to keep the cargo from shifting.

Although a steamship company may have been charging on a certain kind of goods according to a weight basis, they may at any time change to a measurement basis, and this occurs for many reasons. For instance, a steamship company may find that competing lines, either from this country or from Europe, are charging on this class of goods on a measurement basis, and in order to equalize rates the change is made to a measurement basis.

There is no doubt of the steamship company's right to charge on either basis, whichever will give them the most revenue, and the steamship companies do not hold themselves to maintain their rates for any length of time, unless by freight contract arranged between them and the shipper for a stated time. This latter is the only way that a shipper can protect himself against change of rates. During 1915, steamship companies in almost every trade increased their rates, owing to the demand for space and the higher rates they had to pay for the use of steamers which they charter. This made it almost impossible to arrange freight contracts for any length of time.

There is no dividing line as to weight or measurement, above or below which a steamship line will charge on one basis or the other. It is simply a matter of figuring out on which basis they will make the most money, and unless a contract has been arranged, quotations are supposed to apply only on the steamer loading at that time, or the next steamer to be placed on the berth.

FIG. 8—VIEW IN PATTERN SHOP.

tely ninety tons per week. Machine parts of all descriptions, tire moulds, piping, rolls and couplings and general castings for many kinds of work, in addition to material furnished to the machine shop, make up the great bulk of its output. A general view of the moulding shop is shown in Fig. 9, the cupola and core ovens being situated at the far end, while two revolving jib cranes serve the part of the floor where heavy work is moulded. All of the equipment used in the foundry is of Can-

adian make, the cupola being a Sheldons, of ten tons capacity, the cranes and minor equipment being all built locally. plant maintains the factory in a desirable condition of comfort under the most rigorous of climatic conditions. Convenience and reliability of shop operation is secured through the use of Hydro-Electric power, while receiving and shipping facilities are provided by a spur from the G. T. R. tracks, which form one boundary of the company's property. Considerable space is still available for further extensions, and a continuance of the country's prosperity may well necessitate considerations of

Fig. 9—MAIN BAY OF FOUNDRY LOOKING TOWARDS CUPOLA.

adian make, the cupola being a Sheldons, of ten tons capacity, the cranes and minor equipment being all built locally.

such a nature in view of the ultimate development of world trade, which is expected in so many quarters.

THE NEW TERMINALS AT HALIFAX, N.S., AS THEY WILL APPEAR ON COMPLETION.

## Ocean Terminal and Port Development at Halifax, N.S.

By A. J. Campbell

*The effort now being put forth to supplement the natural advantages which Halifax as an ocean port possesses is, although somewhat tardy, visible and tangible evidence that we have now become fully awake to the trade and commerce possibilities in Europe and elsewhere that its all-the-year-round value and facilities not only render available, but that as a matter of fact place all other Atlantic ports on this Continent under a handicap in many respects.*

**T**HE port of Halifax has long been regarded by naval and military experts as the key to the strategic situation in the north Atlantic. In commercial circles a similar opinion is now gaining ground. In suitability of alignment, in width and in depth, the harbor is unrivalled by any competing port on the Atlantic coast of North America. The entrance to the harbor is broad and for fully one-half mile of its width is over sixty feet in depth at L.W.O.S.T. The harbor requires no maintenance, is visible and almost straight throughout a length of seven miles from the entrance light.

### A Natural Harbor

The natural protection and the average low range of tide of five feet, render open piers and tidal basins satisfactory. No such appliances as gates or locks are needed. Ships may enter and leave at any time of day or night with equal facility. The harbor is so easy to navigate—so free from bends and currents—that the largest vessels can enter and leave under their own steam. Recently some of the largest liners afloat, entered, docked and left the port under their own steam and with no assistance from tugs.

The advantageous geographical posi-

tion of Halifax is evident to anyone who has studied the map. The harbor while contiguous to the North Atlantic route to Europe is sufficiently removed from the open shores of the ocean for ample protection. At the same time it is open all the year and is 250 miles nearer to Europe than any other port on the mainland of America. All vessels plying between Europe and such important ports as New York, Boston, Philadelphia, Portland and St. John pass close to Halifax, particularly in winter, and it is therefore most favorably situated as a port of call on the North Atlantic. When the proposed All-Red-Route was being actively discussed, Halifax was regarded on all sides as the best situated terminal point on the Atlantic. Different writers have pointed to its convenient situation on the probable main route from Europe to the Panama Canal. Halifax is the nearest Canadian port and is also nearer than Boston, New York or Philadelphia to seaports on the East Coast of South America, Mediterranean ports and seaports on the West coast of Africa.

### Important Trade Route Terminal

By far the most important trade route in which Canada and the United States are interested is that between

Europe and North America via the North Atlantic Ocean. Most of the exports of the natural products and manufacturers of North America and Europe as well as a fair proportion of these originating in Asia and Africa are carried over this route. The ships employed thereon have long been the largest, fastest and best equipped in the world, and they have steadily increased in numbers and size with the development of the world's trade. Twenty years ago a 10,000 ton liner was considered very large. Now ships of 60,000 tons are in service and plans for larger ones are in progress.

### Ship Sizes and Harbor Accommodation

It is well known that a more rapid increase in the dimensions of ships has been prevented only by the great expenditure and the length of time necessary for the preparation of harbor and dock works of correspondingly increased dimensions. Indeed all the largest ships of to-day are much shallower than they should be for economical construction and operation. Most of the great ports of the world are situated several miles up a tidal river or estuary and the deepening and widening of the harbors and the dredging of their approach channels are slow and costly oper-

ations. The port of Halifax is certainly an outstanding exception. This natural harbor is free from littoral drift at the entrance and, as it has no large river entering, it is exempt from silting or bar formation.

ada and also had considerable experience in the building of terminals in some of the largest ports of the world.

After consideration and comparison of the plans submitted, it was finally decided to adopt a site on the western

fully met for a long time to come.

Tenders were publicly invited for the construction of the first and most important unit of section of the dock works on September 2, 1913. The contract included the dredging of the harbor and basins, filling of reclaimed areas for quays, the construction of one and a quarter miles of concrete and granite masonry quay walls, concrete substructures for the transit sheds and buildings, sewers and other incidental works. The tender of the well-known firm of Foley Bros., Welch Stewart and Fauquier amounting to \$5,250,000 was accepted.

#### Construction Work Begun

The contractors began work in March of 1914 and operations have continued since that time. The great depth of water and the somewhat unusual nature of the work required the use of a large amount of specially designed plant. Eighty-five acres of the shore land were expropriated, which with 115 acres reclaimed from the harbor makes a total area of 200 acres available for the terminal yards, quays, piers, etc. The area of water to be occupied by shipping inside the new pierhead line will be sixty-two acres. The distance between the pierhead lines and the opposite shore of the harbor is one mile and the depth of water seventy feet at L.W.O.S.T. In front of the terminal site there is therefore provided by nature free of cost a magnificent canting station one mile square and at least seventy feet deep perfectly protected from the ocean and

VIEW OF THE HARBOR—CELLULAR CONCRETE BLOCKS IN FOREGROUND.

Almost from the founding of Halifax in 1749, the matter of wharfage and terminal facilities has been one of constantly recurring urgency. In recent years the principal wharfage facilities have been provided by a number of timber piers constructed at the Northern portion of the water-front known as the "Deep Water Terminals." In addition a reinforced concrete pier has been erected there, a description of which has already appeared in these columns. Even with this addition, it was felt that sufficient provision was not made for the existing and prospective needs of the port. In the last decade there has been not only a marked increase in the dimensions and speed, but also in the class of ships employed between Canadian and European ports, and there is every prospect that this improvement will keep pace with the phenomenal development of Canada which is looked for after the war.

#### Initiation of Development Scheme

Plans for a comprehensive scheme of terminals were begun by the Dominion Government in the summer of 1912. After an exhaustive survey of the situation, four alternative plans each with its own advantages and disadvantages were presented by the engineers employed. These gentlemen were F. W. Cowie, B. Sc., M. Inst., C.E., of the Montreal Harbor Commission as consulting engineer, and James McGregor, A. M. Inst., C.E., A.M. Can. Soc. C.E. as president and superintending engineer. Mr. McGregor had previously been with the Canadian Pacific Railway on construction work in Western Can-

shore of the harbor and nearer to the ocean than any of the old piers. The site extends southward along the water front for a distance of one and a quarter miles. This location was considered to be the most desirable with regard to the city population and industries, and sufficient ground was taken for the extensions of the future. The adopted scheme of piers, basins and railway terminal facilities was prepared with a view to

CLOSE VIEW OF THE CELLULAR REINFORCED CONCRETE BLOCKS.

a progressive development extending over a period of years so that the future traffic requirements of the port may be

remarkable free from winds and currents and an ideal situation for the turning and manoeuvring of ships of any pres-

ent or proposed length, breadth, draught, or displacement.

The quays and piers were planned to provide twenty-seven berths for ships varying in length from 500 to 750 feet each, but ships up to 1200 feet in length

most required. It is expected that three berths in Basin No. 1 will be ready for use next winter and that two temporary wooden sheds will be ready for use on the north quay of same. The excavation of the railway yards at the dock is well

Each of the five piers and six basins will be 1250 feet long and will taper from 320 to 360 feet in width. The piers are designed for four 600 foot ships, two on each side, or for two ships each up to 1200 feet long, one on each side and with no part of either ship projecting beyond the pierhead line. The basins will have a minimum depth of forty-five feet at L.W.O.S.T. This is five feet deeper than that provided at New York or Southampton and ten feet deeper than at Boston. The rubble mound breakwater at the seaward end has a quay wall on the inner side 1205 feet long and an open rip-rapped slope on the outer or seaward side protected with heavy blocks of rubble.

#### Quay Wall Features

Quay walls of concrete and granite will be constructed along the lines of the bulkhead landing quay, basins and piers, while the areas between the respective walls, and between the walls and the shore, will be filled in with materials from the railway excavations, dredged materials from the basins, and materials secured by dredging from the eastern side of the harbor. About one-third of the total length of quay wall is constructed and about sixty per cent. of the foundation work for the remainder completed. The dredging of the basins and for the quay walls is ninety per cent. completed. This dredging was done by means of a dipper dredge with a seven cubic yard bucket to a depth of forty-five feet below low water. As greater depth the dredging was done by a very heavy orange peel bucket of five

THE MOBILE PNEUMATIC CAISSON EMPLOYED.

can be accommodated with equal facility. Provision is also made for the berthing of coasting vessels and other smaller craft. The basins are suitably arranged for ships to pass in and out, and for the use of coal and other barges alongside.

#### Meantime Scope of Undertaking

The first unit of the docks now under construction will include the Bulkhead Passenger Landing Quay, North Quay of Basin No. 1, and the Bulkhead Quay of Basin No. 2, and will provide berthage with sheds etc., for nine ships of the Alsatian type. All these structures together with the breakwater have been carefully laid out along orthogonal lines to simplify construction and so as to concentrate within a comparatively small area a maximum of quay space and berthage with ample transit sheds and buildings, and with convenient and adequate truckage and paved driveways to each berth. The piers and basins are laid out at right angles to the shore line, and also to the direction of maximum fetch and exposure.

The breakwater at the extreme south protects all the piers and basins to the north of it from the south and south-east which are the only directions from which seas of any weight can enter the harbor. With the exception of Basin No. 1, all the piers and basins will be of the same dimensions and area. The basins are widened out towards the harbor and the piers toward the land, thus effecting a saving in cost of construction and affording extra width where

advanced, and sufficient trackage will be provided there next winter to deal with the traffic to and from the three berths at Basin No. 1.

#### Bulkhead Passenger Landing Quay

The Bulkhead Passenger Landing Quay will be 2006 feet long, sufficient to accommodate three ships 650 feet long or two ships 1000 feet long. It is situated at the north end of the works nearest

CELLULAR CONCRETE BLOCK BEING PLACED IN POSITION.

to the centre of the city and adjoining and directly connected with the Union Passenger Station to be constructed.

and one-half cubic yards capacity. The rock in the basins and under the quay walls was drilled by Keystone well

drills, blasted with dynamite, and afterwards dredged. The method employed in constructing the quay wall is described by Mr. McGregor as follows:—

The quay wall, is for the most part, founded on solid rock but where the depth of rock exceeds 55 feet below L.W.O.S.T. a broad rubble mound foundation is used, the top of which will be at 45 feet below L.W.O.S.T. The walls are constructed of cellular reinforced concrete blocks each about 31 ft. by 22 ft. by 4 ft. 1½ inches, with outside walls and partitions 8 inches thick, each block weighing about 62 tons. All the cells in the bottom blocks and the front and centre cells only of all the other blocks are filled with concrete. The remaining cells are filled with rock, sand and gravel from the excavations. The cellular blocks at the front reach to a height of 1 foot below extreme L.W.L.,

22 feet, each length consisting of a vertical stack of 13 cellular blocks. In this way the block setting is very simple, and allowance is made for settlement and expansion and contraction. The vertical joints between the stacks are made with vertical reinforced concrete key posts 14 ins. by 14 ins. in section, which also act as guides in adjusting and setting the blocks. The bottom was cleaned and made ready for the mass concrete by means of a self-submerging raising and floating steel and timber diving bell specially designed for this work. This diving bell or mobile pneumatic caisson has a working chamber 38 ft. by 26 ft. by 8 ft.; has separate man and material shafts and air locks, and can work safely with compressed air to a depth of 55 feet of water. It is lighted with electricity and provided with high pressure air and water sys-

tem in the open, and at various elevations, it was decided to extend the railway in the open from Fairview, via the east side of the North West Arm. The contract for construction was awarded on July 2, 1913, to the Cook Construction Co., and Wheaton Bros. The tender amounted to \$1,500,000. Work was at once begun at both ends of the line and has since proceeded slowly but surely through the heavy rock cuttings. The contractors have a well-organized force and an efficient plant in use, including five complete steamshovel outfits. The contract included the filling in with materials from the railway cuttings and the formation of a new terminal freight yard at Bedford Basin, grading of a portion of the ocean terminals, and the formation of the rubble mound breakwater also with rock excavated from the cuttings and yard areas. This breakwater will be completed during the present summer.

The new railway line which is about five and a half miles long will be double-tracked throughout and sufficient right-of-way has been acquired for four tracks should more become necessary. The construction of the culverts and bridges of a permanent character is being proceeded with. Grade crossings have been entirely eliminated. In the location of the railway along the beautiful Arm and through one of the finest residential districts of Halifax, care has been taken to preserve as far as possible the natural scenery. The cut is now practically ready for the rails and it is expected that track laying and ballasting will be begun this summer, so that the railway connections will be ready for use in connection with the three berths next winter. The work of trimming off the sides of the cutting is at present in progress. Over two million cubic yards of material have been excavated and transported to be used as fillings elsewhere. An eighty-five pound rail will be laid.

#### Freight and Passenger Arrangements

All freight trains to and from Halifax will be cared for at a new Freight Receiving, Classifying and Departure Yard. This yard is being constructed on an area that has been reclaimed from Bedford Basin, by filling in and has a length of one and a quarter miles. The filling in is nearly completed and the track laying and ballasting of the whole yard will be ready in time for next winter's traffic. All freight cars will be moved between this new freight yard, the Ocean Terminals, the city freight yards and sheds, by switching and transfer engines.

The general scheme for the Passenger Terminals consists of a large passenger station building shaped like the letter

VIEW OF CUTTING SHOWING TEMPORARY BRIDGE FOR STREET.

and at 4 ft. 8 in. back from the face they are continued with narrower blocks up to 1 foot above H.W.L.

Above this the construction is of rubble concrete faced with cut granite masonry beginning with a heavy corbel course and finishing with a granite coping 3 ft. wide and 16 inches deep, with the exposed arrises rounded to 2½ in. radius. The joints are secured with secret steel dowels. The back of the wall has been vertical to simplify the blocks carrying the front columns of the transit sheds, and to provide width on top to carry the permanent railway track as well as the temporary construction tracks for the block setting machines which will lay the blocks by the "Over End" system. These travel outward upon the blocks as they are placed, and so eliminate the use of temporary staging of floating plant. The front of the walls is made vertical and the toe projection reduced to a minimum to suit the almost rectangular midship section of modern large vessel.

The walls will be built in lengths of

22 feet, each length consisting of a vertical stack of 13 cellular blocks. In this way the block setting is very simple, and allowance is made for settlement and expansion and contraction. The vertical joints between the stacks are made with vertical reinforced concrete key posts 14 ins. by 14 ins. in section, which also act as guides in adjusting and setting the blocks. The bottom was cleaned and made ready for the mass concrete by means of a self-submerging raising and floating steel and timber diving bell specially designed for this work. This diving bell or mobile pneumatic caisson has a working chamber 38 ft. by 26 ft. by 8 ft.; has separate man and material shafts and air locks, and can work safely with compressed air to a depth of 55 feet of water. It is lighted with electricity and provided with high pressure air and water sys-

#### Transit Sheds

The transit sheds on the quays and piers will be built of steel and concrete. Each will be 100 feet wide and will be fully equipped with the best mechanical appliances, water supply and fire protection, offices, coaling facilities, grain conveyors, railway tracks, paved roads and teamways etc. Cargo sheds will be provided at the passenger landing quay where also special appliances and facilities will be installed for the expeditious landing of passengers, baggage, mails and express freight from the ships to the trains, and vice-versa. A large terminal grain elevator with ample trackage and fully equipped with belt conveyors and spouts will be erected.

#### Railroad Connections

To obtain the necessary railway connection for the new terminals, an extension of the Intercolonial Railway is necessary. After the comparison of several alternative lines in tunnel and

T—the foot of the T being at the shore end and the head on the landing quay. The shore end will provide accommodation for the local Halifax traffic, and will contain the ticket offices, baggage and parcel checking rooms, restaurant and lunch rooms, retiring rooms with toilets, and, on the upper floors, office space for the railway and steamship lines. The shore end of the building will face on a plaza 400 feet in depth. Upon the northern end of the landing quay the top portion of the T-shaped building will be placed. Passengers disembarking from the steamships will enter the building at the second story level and will be distributed in the usual way for Customs examination. The baggage will be transferred, after examination. The baggage will be transferred, after examination, by means of chutes or elevators to a distributing baggage room below, from which it will be routed to cars according to destination.

Mails will be conveyed directly from the steamships to the lower level where they will be loaded on cars. Passengers pass conveniently into an apartment between the steamship station and the Halifax City station, forming the stem of the letter T. This is a booking hall containing ticket offices for the various railway, and steamship lines where passengers may quickly and easily obtain railway tickets and baggage checks. They can then either step into the train concourse or into a waiting room.

#### Train Concourse

The train concourse is designed for the common use of the Halifax City traffic and the steamship passenger traffic. The floor of this room is placed level with the second story of the steamship passenger level and is also at the same level as the ticket lobby floor of the Halifax city station. The passenger platforms of the train shed are placed at a level midway between the train concourse and the baggage room beneath. Passengers will reach the passenger platforms from the train concourse level by means of easy inclines instead of stairways. Separate inclines and separate trucking platforms for baggage trucks are provided. A portion of the building will be reserved for the Immigration service. These rooms are not directly connected with the other portions of the station building.

#### Miscellaneous

The other general arrangements include a separate power house for the furnishing of heat, light, and power for all the buildings. A large passenger coach-yard fitted with buildings for cleaning coaches and equipping dining and sleeping cars will be provided immediately adjoining the passenger sta-

tion. A broad subway for vehicular traffic will be constructed to pass under the freight and passenger tracks connecting with a broad-paved roadway leading to all the steamship berths and the main city thoroughfare. The grading for the site of this building is now in progress, and construction will be begun at an early date.

#### PROSPECTS FOR TRADE IN RUSSIA

WITH further reference to articles that have appeared in our columns on trade with Russia, the following extracts taken from the Board of Trade Journal and the United States Commerce Reports may be of interest to Canadian manufacturers anticipating an export business in that country:

##### A Few Facts

It should be borne in mind that the great bulk of the local dealers in the Caucasus are people with little or no capital. A condition, therefore, which is essential for the successful expansion of trade is that it has to be carried on with the support of banks which advance money on goods. This is more especially the case as regards the export trade in raw materials. Dealers have, of course, to pay a fairly high price for this pecuniary aid, but the arrangement enables them to handle a great volume of merchandise, and it pays in the long run. In the import trade, German manufacturers frequently gave financial assistance, more especially to small dealers, by a system of credit which met with the latter's approval and was extensively resorted to by them.

##### Meeting German Competition

The question of successful competition with German firms after the war is of great importance, and the present time is a favorable one for activity by Canadian manufacturers. They should enter the field now, if only for the purpose of making arrangements preliminary to actual business after the war. Manufacturers should send out travellers speaking Russian, with price lists in Russian, prices being worked out in roubles at the current rate of exchange. The travellers should carry samples of all the goods which it is desired to sell, and get into touch with dealers. Manufacturers of other countries are quite alive to the necessity of action of this kind and are very alert just now in the Russian markets. It is intimated that in the long run these suggestions, if acted upon, will prove remunerative. Dealers in the Caucasus repeatedly say that they have neither the time, the means, nor the desire to enter into lengthy explanations by correspondence. They have been accustomed to the visits of commercial travellers who show them samples of the goods they have to sell and are prepared to book orders on the spot. The great bulk of the traders con-

sider that catalogues should be brought to them and explained. As the information contained in catalogues would be of use if they were judiciously distributed, it is suggested that copies should at least be put into the hands of the dealers.

#### Electrical Appliances and Materials

The electrical trade is a branch of Canadian industry that might very profitably be developed in the Caucasus. Until the outbreak of war, and for some time after, the electrical engineering appliances and materials required locally came principally from Germany. If the intention to capture German trade under this head is to be realized, Canadian manufacturers should take advantage of the present opportunity to prepare for the competition that will exist after the war. The needs of the Caucasus in all manner of electrical appliances from the smallest to the largest are indeed very great, and when normal conditions are resumed there is no reason whatsoever why Canadian and British sources of supply should not be preferred to those of Germany. The quality of the articles produced there is admitted in the Caucasus to be superior to that of German-made goods, but the question of price will have to be studied closely, together with that of the terms of payment. At present most supplies are almost exhausted.

#### Agricultural and Other Machinery

The possibilities in these branches of trade in the Caucasus are also great. Necessarily, in view of prevalent conditions, no imports under these two heads took place in 1915, but directly after the war the demand for every kind of machinery will be brisk, and this remark is particularly commended to the attention of Canadian manufacturers of machinery.

##### Cutlery, Hardware, etc.

All stores in the Caucasus are almost depleted of their stocks of hardware. The need for goods of this description is very great, and a large business will be done directly after the war. Our manufacturers should be on the alert as American firms are watching their opportunity for getting a strong footing in the Russian hardware markets. As it is, trade in this class of goods with the United States is already extensive.

#### THE SHIPPING OUTLOOK

AT the recent meeting in London of the Royal Mail Steam Packet Co., Sir Owen Philipps, the chairman, among other things, said:

"Many smaller shipping companies owning tramp steamers have recently been paying very large dividends, as a result of the high rates of freight obtainable in the open market, but the

erating under the lease system, much of the necessary equipment can be purchased outright.

During the early period of machine-made footwear, much trouble was experienced, owing to the various types

ments, until it had a system of machinery for attaching the soles to shoes (universally known as the "Goodyear Welt") which, in comparison to the product of former years, is truly marvelous. All of this was accomplished only

the most minute screw, the magnitude of this undertaking can be readily comprehended.

The company maintains in each of its branch offices, a corps of men who, in addition to being skilled mechanics, are expert shoemakers as well; competent to repair the machines and give reliable instruction in their operation. The company is impartial to all of its customers, each one knowing that he is not only entitled to, but actually receives the same service as his competitor. It has been a cardinal principle in the building of the company's business to play no favorites, and the sincerity of the company's efforts is apparently never questioned by its customers.

#### Success of the Undertaking

The United Shoe Machinery Co., of Canada, has apparently been successful in performing the things it set out to accomplish, for the boot and shoe industry has prospered as at no other time in its history. The company has been constant and diligent in anticipating the requirements of the industry it has served so well. From the small space it occupied, on the top floor of an old building, during the first year of its existence, the rapid growth and expansion of the business has culminated in the erection of what is considered one of the best equipped and arranged factories in Canada. Located in the Maisonneuve district of Montreal, it was designed to meet not only the immense requirements of the company's business—due to the large number of different machines of an extremely intricate

GENERAL VIEW OF MACHINE SHOP FROM WORKS OFFICE.

and makes of the machines then in use; parts would wear out, adjustments go out of order, causing long and vexatious delays, and frequently causing plants to shut down until the machine could be repaired and placed in proper running order. Most of the machines then being used were made in or near Boston, and in addition to the terms imposed by the maker, custom charges, and all expenses relative to operating instruction made it almost impossible for boot and shoe manufacturers in Canada to compete with other makers abroad. Under these conditions, it is not surprising that this industry, in Canada advanced but slowly. Many manufacturers preferred to cling to such primitive means as the awl, waxed ends and hammer—shoe-making tools as old as the Egyptian temples—operating only such machines that required little adjustment or mechanical attention, rather than submit to existing conditions.

#### Canadian Development

Such was the state of affairs when in 1899, the United Shoe Machinery Co., of Canada was formed, an event which undoubtedly transcends all others in the history of an industry which, in its evolution from the purely hand process and implements of only half a century ago, has passed through many revolutions, many of them almost spectacular in character. The United Shoe Machinery Co. of Canada established its factory in Montreal, secured a number of the best machines then in use, improved them, designed and constructed others to fill in the gaps for which there were no machines. It harmonized their action, adjusting them to each other's require-

at the expenditure of much money and untold effort. To maintain the best possible relationship between themselves and their customers, this firm not only supplied the desired equipment, but made provision for keeping it constantly in good working condition. It established branch offices in Quebec, Toronto and Berlin, where a complete supply of machine parts were always available for immediate use, thus insuring to the utmost against any possibility of delay in

GENERAL VIEW OF ASSEMBLY ROOM.

operation of a factory in the various territories. When it is realized that this company, in the regular routine of its business, makes over 83,000 different kinds of machine parts, varying from a machine base, weighing over a ton, to

nature it manufactures—but to provide for future needs. It is the basis of the highly organized and efficient service, which is distributed through its various branches, and is ever at the disposal of its many customers throughout Canada.

### New and Modern Building

The main building, four stories high, is 280 feet long and 60 feet wide, with a wing leading to a one-storey building in the rear. The ground floor of the main building contains the parts department

VIEW OF TACK AND NAIL DEPARTMENT.

and shipping department; the second floor, the assembling department and general offices; the entire third floor is used for the machine shop and works office, with the woodworking and draughting departments on the fourth floor. The one storey section in the rear is used for the tack factory, the die factory, the blacksmith shop and boiler room.

As one passes into the main entrance, he is immediately impressed with the regular and convenient arrangement of the various offices, and also the extensive and efficiently arranged general office. The furniture is modern in every respect, and of the latest design. All office stationery, both for the head office and the several branches, is under the supervision of one person, and is kept in such a manner that a constant record is maintained of the stock on hand. Each form or requisition blank pad, when printed, receives its particular stock number, as well as the date of printing, so that a record can be kept and when a further supply is required, the date will indicate whether the previous lot was sufficient or not enough. Provision is made for a six months supply, as it is deemed inadvisable, owing to possible changes, to carry a heavier stock. Under the present system a saving has been shown of thousands of dollars a year.

All letters are filed away in a special room reserved for this purpose, with a girl in charge whose duty it is to keep tab of all correspondence received. The only entrance to this room is through that of the manager, and it is almost impossible for anyone to secure a filed letter without the knowledge of the girl in charge.

Adjacent to the main office is a rest room, with piano, which the company provides for the comfort and conveni-

ence of the office employees: there is also another small room adjoining this where light cooking can be done should any of the girls desire it, all necessary utensils and equipment being furnished by the company.

### Machine Shop and Works Office

The machine shop which, with the works office, occupies the entire third floor contains in all, 131 machines, consisting of milling machines, lathes, drills, screw machines, boring machines, boring mills, shapers, planers, grinders, cam cutting machines, profiling machines, etc.

In this plant, 125 different types of shoe machinery are manufactured, and some idea of the extent of this industry can be gathered from the fact that some of these machines are using as many as 750 different parts, and the total num-

in the background; another view shows the section containing the various grinders with the lathes in the background, the machine in the immediate foreground being a product of the shop, an automatic heel compressing machine.

In the centre of the two sections, is located the works office which keeps a record of all the work, detail and assembly, as it passes through the shop. This is a very important feature in connection with the operation of this plant, and much of the success of this company is due to the thorough manner in which even the smallest detail receives attention, reducing to a minimum any possibility of loss or error. Particular attention is drawn to the general appearance of all sections of the shop: complete absence of waste material; order and cleanliness of the general equipment; sanitary conditions, etc. The room is entirely free from any objectionable dust, and even amidst the every-day grind of machine shop operations, this works office retains its appearance of order and cleanliness, to such an extent that it would be a credit to many a main office in other manufacturing plants.

### Machine Assembly Room

The general assembly room, a view of which is here shown reflects in some measure the numerous machines being manufactured and the marvellous quantity of different parts required in the complete assembly of the final product. This room is supplied with a number of one-ton chain blocks for facilitating the erection and handling of the heavier portions of the machines under construction; the one in the centre aisle travel-

VIEW OF MACHINE SHOP, SHOWING UPRIGHT AND MULTIPLE SPINDLE DRILLS.

ber of parts manufactured at this factory for their numerous machines will aggregate approximately 25,000. Several views of the machine shop are here shown; one illustrating the upright and multiple drills, with shapers and planers

ing on a girder running the full length of the room, and those in the side sections operating on the ordinary ceiling girders. No unnecessary material is allowed to accumulate upon the floor, the required number of parts being

erating under the lease system, much of the necessary equipment can be purchased outright.

During the early period of machine-made footwear, much trouble was experienced, owing to the various types

ing on a girder running the full length of the room, and those in the side sections operating on the ordinary ceiling girders. No unnecessary material is allowed to accumulate upon the floor, the required number of parts being

secured from the parts department for the assembling of each machine. A complete supply of about 40,000 different parts is constantly kept in stock, to avoid all possible delay in maintaining the high standard of efficiency in the company's service department.

#### Tack and Nail Department

The tack and nail department which is continually turning out hundreds of thousands of tacks and nails every hour is here shown, giving some idea of the general layout of the equipment; the nail machines being on one side and the tack machines on the other. Driving motors are supported on special platforms, hung from the ceiling. Neatly arranged racks and bins to hold the stock are located in convenient positions, and special trays are provided of each machine.

#### The Blacksmith Shop

The blacksmith shop, to the rear of the tack and nail department is fully equipped for making all the dies and tools required for the production of the various styles, shapes and sizes of the different shoes. Oil burning furnaces are used for heating the pieces, and cooling and tempering baths are arranged so as to insure the best results in the handling of material. Tempering tanks are provided with water coils to regulate the temperature of the bath.

#### General

Machinery and shafting throughout the plant is driven by 12 induction motors, capacity ranging from  $2\frac{1}{2}$  h.p. to 35 h.p.; Renolds silent chain being the transmission medium from the motors to the line shafting.

GENERAL VIEW OF MACHINING DEPARTMENT.

Individual wash basins in the dressing rooms and clothes racks are provided for the workmen. A restaurant with seating capacity for one hundred is also furnished, meals being served at a very

moderate cost and the best of service constantly maintained.

The number of men employed in the various departments of the factory is approximately three hundred, and while their interests outside of their

ANOTHER VIEW OF MACHINING DEPARTMENT. NOTE HEATING COILS UNDER SKYLIGHT.

work vary, they appreciate the value of exercise and recreation, their efforts in this direction finding ample scope in the works Athletic Association which holds its meetings in extensive grounds supplied by the company and maintained in a state of perfection matching that of the works themselves.

#### UNITED LAST COMPANY PLANT

TO meet the requirements of their rapidly increasing business, and at the same time prepare for future needs, the United Last Co. have recently completed

while operating under separate management, are still indirectly connected, both being directed by the same parent company.

The main building is of mill construction, 140 ft. by 140 ft., one storey high,

with basement. The main floor contains the machining department, office and sample room; while the basement contains the supply of rough-shaped blocks, a vault for the storage of standard models, lockers and washrooms, etc.

#### Rough Stock Department

The stock bins are very extensive, 400,000 rough-turned blocks being constantly kept on hand. These blocks are received from cars at the rear of the building, and are placed in the various bins according to their size and style. These blocks are generally made of kiln dried maple, with a supply of ash blocks to be used for making up travelers' samples. These when finished are exact duplicates of the standard lasts, but for obvious reasons are made of a light wood and hollowed out for convenience of handling. Owing to the nature of the work, this room—in fact, the entire building—is kept at an even temperature of about 68° F., being regulated slightly to conform to the general humidity.

#### Machining Department

On this page are shown two views of the machining departments, where the rough blocks are rapidly converted into finished and faultless lasts. The equipment consists of 22 turning lathes, with all the additional machinery necessary for an output of 1,000 pairs per day. By means of a standard style model, invariably of the right foot, the lathes will turn out either right or left foot lasts, and of any desired size or width, simply by the adjustment of various cams and levers. After the lasts have been rough turned, the heels and toes are dressed off in specially designed machines, which can be so adjusted by cams, etc., to automatically shape the parts to the

the erection of a new factory of the most modern type in the City of Montreal, adjacent to the extensive plant lately constructed by the United Shoe Machinery Co. These two concerns,

desired size and style. Holes for the hinge joints are drilled and counter-bored, lasts are sawn in two, face of joint tongued and grooved to insure proper alignment, spring hole drilled, etc., continuing on until the final buffing and polishing operations complete the lasts. Each succeeding operation is gauged from the first drilled hole, so that each last is an exact duplicate of its fellow.

#### Model Making Department

Of recent years the efficiency of last making has not only increased, but it has been necessary to meet the requirements of the trade in the wide range of shapes and styles that are continually being adopted. When a new style has been decided on, the design is taken to the model making department, where an accurate sample is made by hand. If approved by a customer, an exact duplicate is made and deposited in a fireproof vault in the basement, where all the models, of every last made, are kept with the various master patterns of that particular make of shoe.

#### Upper Patterns

In addition to the machining of the wooden lasts, two high-speed Reed grading machines are used for cutting out the patterns of the various upper parts. The action of these machines is similar to the last turning lathes, inasmuch as the grading of the different sizes of the same style of upper part is derived from the same master metal pattern, secured to the machine, so that by moving a gauging finger around its edge, the cutter, revolving at a speed exceeding 30,000 revolutions per minute, cuts the

#### Dust Removing System

The title cut shows an exterior view of the plant with the power house on the left. Above the main building and passing over to the boiler room is seen the system of pipes and receivers that carry

DIE DEPARTMENT WITH SMITH SHOP IN REAR.

the dust and shavings from the various machines and benches to the boiler room, where the waste material is consumed in the boiler furnaces. It will be noticed that another smaller system is arranged at a lower level and leading to a separate receiver. This leads from the buffing and polishing machines, where there is the possibility of a live spark setting fire to the waste material. By using a separate system to convey the

feature in connection with this plant is the compact yet efficient manner in which the power house equipment is arranged. The boiler house equipment consists of two 250 horse-power water tube boilers, each fitted with Foster

superheaters, and two 3-in. Consolidated pop safety valves. The boilers are hand-fired, grates being No. 3 McClare Brooks, 7 ft. by 7 ft. 6 in.,  $\frac{3}{8}$  in. mesh, fitted with twin lever. Thompson damper regulators are also fitted to both boilers. Two  $7\frac{1}{2}$  in. by  $4\frac{1}{2}$  in. by 10 in. duplex piston pattern, feed water pumps, bronze fitted, of Worthington make, supply water to a Blake Knowles steam stack, cut out, water heater. Steel piping, with C. G. E. E. fittings and Lunken-

heimer valves are used; steam traps are Anderson low pressure type.

The engine room contains a four-stage condensing Curtis turbine, direct connected to a 600-kilowatt generator, running at a speed of 3,600 revs. per min. This unit is operated in conjunction with an Alberger surface condenser, having a cooling surface of 2,400 sq. ft., equipped with an 8-in. regular volute centrifugal circulating pump, driven by 5 in. x 6 in. vertical Sturtevant engine. There are also one 6 by 14 by 10 in. Alberger horizontal air pump, and one 2 in. Alberger hot well pump. The circulating water is cooled in a large cooling pond, equipped with spraying apparatus installed by the Spray Engineering Co.

The building is equipped with sprinkler system throughout, and in addition, a highly efficient fire-fighting squad has been formed among the workmen. The comfort of the employees is well looked after, individual lockers being supplied, as well as wash basins, shower baths, etc.

#### THE CEMENT INDUSTRY

ABOUT three-fifths of the cement imported into Ecuador used to come from Germany. The demand for cement is increasing chiefly on account of the sanitation work now in progress in Guayaquil, and also on account of the erection of the new municipal buildings, for the law requires the foundations of all new buildings to be constructed of concrete. It is worthy of notice that the superior quality of the barrels used by the United Kingdom exporters greatly reduced the percentage of loss of material in transit.

400 K.W. TURBO-GENERATOR AND CONDENSING PLANT.

pattern from the mill board sheet. These two machines have a capacity of about 1,000 pairs per day. The patterns are afterwards edged with a tin or brass facing to protect them from the cutting knife.

dust from these machines the danger of fire is materially reduced.

#### Power Plant

The power house is located at the rear of the main building. An outstanding

### WORLD-WIDE PROGRESS FOLLOWING THE WAR

**O**PTIMISTS continue to lay stress on the ultimate expansion of the world's trade and to emphasize the necessity of seizing every opportunity to lay a present foundation for future operations. Some of these critics have referred to the records of historical commentators as authority for the statement that many of the world's advances in arts and industry took place during former periods of strife, the progress of England as a manufacturing nation during the Napoleonic war being one of the outstanding instances of such economic phenomena.

While it is no doubt pleasant to draw comforting analogies between the present and past wars, the wish may be father to the thought to such an extent that accuracy may be overlooked. In many ways the present world condition is entirely unparalleled by any former occurrence. In the instance referred to, England had been enabled, as a result of the unsettled state of affairs in Europe, to obtain a considerable lead in many industries, this being rendered further valuable by her overseas commerce which was then attaining considerable dimensions.

Viewed in the light of the present tumult, however, conditions then were much more favorable to making an advance over industrial competitors than now, one reason being that outside of England there were few aspirants to overseas trade, whereas at the present moment every neutral nation is straining to secure and retain much of what was formerly British business. The strides being made by Scandinavia and Holland in the motor ship industry are one example alone which causes more than passing concern, yet to those who endeavor to see further and deeper than the present trend of events, the possibility of British trade being permanently or even seriously menaced by such developments seems remote.

Latest advices from the scene of hostilities indicate that the industrial resources of the Allies have been utilized to an extent well nigh incredible. While the output of war material in Britain is vast beyond comprehension, the significance of such efforts as omens of future

activity should not be lost sight of by those concerned with future happenings in the industrial world, and students of history are not altogether lacking in data wherewith to demonstrate the repetition of the past. The past eighteen months have witnessed developments in every branch of physical science which in ordinary times would have excited the wonder of the world, but at the moment receive only passing comment. Trans-Atlantic telephony, high-speed steel without the use of rare metals, the commercialization of many processes hitherto only possible for the manufacture of products of formerly limited demand, advances in the design, material, and methods of manufacture of airships and submarines, etc., stainless steel, non-ferrous alloys—these, to mention a few only, are some of the more obvious developments whose ultimate influence on industrial conditions will only begin to be felt when ploughshares and pruning hooks resume their natural and inevitable positions of importance in the structure of civilization. In former wars Britain only, advanced, in this war Britain and the world advances.

### FACTORS IN OUR MUNITIONS PRODUCTION

**F**ROM observation covering many of our munitions manufacturing plants we have been impressed with the grim earnestness and methodical application which marks each operator's activities. There seems to prevail a keen sense of the necessity for absolute fitness of the product, whether the realization have its inception because of a piecework or bonus system of remuneration in vogue; the strictness of the individual piece inspection; or the desire transcending both of these, that the product may in no respect fail of its great and ultimate purpose. Whatever be the reason, and all three suggestions are likely to be more or less contributory, it would appear that employer and employee are less widely apart in their aims and ideas than pre-war times seemed to indicate.

If there is one thing more than another that munitions production has demonstrated — we speak from what we have seen and experienced in Canadian plants, it is the absolute necessity of having departmental oversight, and that again, of course, in the hands of men, tactful, resourceful and resolute. Such men are rather less plentiful than recruits for our overseas battalions—in any case their sphere does not meantime belong there.

The success of many of our munitions manufacturing plants and the spirit actuating their humblest operator is altogether attributable to headquarters and departmental administration of the nature indicated. Although the language is admittedly figurative, we know of cases where the salary limit of departmental supervisors was given as the "sky," provided the men could be got; and in the particular instances, as is nearly always the case when the position seeks the man, success crowned the enterprise.

The smooth-running, intensified and accelerated munitions output which to-day characterizes our metal-working plants constitute perhaps the most noteworthy achievement that industrial Canada has meantime on record. Of greater importance, however, is the indication that she is out for further achievement both at home and abroad, and means to realize it.

The decision to enter some department of overseas trade should be reached only after due deliberation involving a full accounting of the cost, and with a stolid determination to surmount not only the initiation difficulties, but those incidental to subsequent procedure.

## INDUSTRIAL NOTABILITIES

**T**HOMAS JOSEPH DILLON, director, Canada Foundries and Forgings Ltd., Brockville, Ont.; president, Canada Forge Co. and general manager, Canadian Billings & Spencer Ltd., of Welland, Ont., was born at Indianapolis, Ind., July 12, 1882, the son of John T. and Katherine (Hanley) Dillon. He was educated in the public and high schools, and started his business career as apprentice with the Titusville Forge Co., Titusville, Pa., in 1896. He passed through the various departments, emerging as a forging specialist in 1905.

THOMAS JOSEPH DILLON

Mr. Dillon came to Canada in the latter year, and organized the Canada Forge Co., becoming its president, and being more than anything else responsible for the plant growth and product achievement as we find it to-day. In 1912, when the merger of the James Smart Co., the Canadian Billings & Spencer Co., and the Canada Forge Co. took place, Mr. Dillon became a director of the combination.

He married Edith Maude Burgess, daughter of Charles Burgess, proprietor of the Cyclops Steel Co., Titusville, Pa., on November 23, 1904, there being two sons and two daughters of the union.

Mr. Dillon's recreations are golf and motoring, his Clubs the St. Catharines, Welland; and his Societies, the Knights of Columbus. In religion he is a Roman Catholic, and his residence is 122 Hellem Avenue, Welland, Ont.

creased production here. In all other lines, the productive end is very active but the market is very quiet.

## Metals

The situation in metals shows very little change, and the general market is quiet. Copper is fairly steady but inclined to weaken. Tin is at present firm but is expected to weaken in view of heavy supply. Spelter is still falling off, and lead prices may be subjected to re-adjustment in the near future. Antimony is very weak and aluminum is a little easier.

**Copper.**—The market is not very active, and under the conditions prices are almost stationary. Producers at present show no inclination to reduce prices, awaiting the trend of present developments. The turn of affairs recently shown in reports from the other side, foreshadows, some changes in the metal situation. London reports a little strength during the past week, advances of £5 and £4 being shown in standard spot and futures; quotations being £103 for spot and £100 for futures. Eastern price c.i.f. London of £3 15s. over last week. With the exception of lake, which shows an advance of ⅛ cent, New York prices are firm; this weeks quotations being 27 cents for lake, 26⅞ cents for electrolytic and 24¼ for castings. Local conditions are unchanged and dealers report a quiet market at last week's prices, 31 cents for lake and electro and 30½ for castings.

**Tin.**—The situation in tin continues to be very quiet and little activity is shown. Recent arrivals of tin have placed considerable metal on hand, and in view of the fact that large consumers are well covered for immediate and early requirements, buyers are showing very little interest at any deliveries. London prices are easier while New York prices show a decline of ⅝ of a cent the nominal quotation for Straits tin being 39⅝ cents for pound. Unchanged conditions prevail in the local market and dealers are still quoting 47 cents per pound.

**Spelter.**—The market is quiet and prices are still declining, the production of spelter being far in excess of the present demand. The New York market has declined ⅞ of a cent during the week, the nominal price now being 11 1-3 cents per pound. Local dealers report a dull market on declining prices, present quotations of 15 cents being a decline on the week of one cent per pound.

**Lead.**—The situation in lead maintains a steady position and prices are holding firm. Outside interests are still slightly below the Trust prices and are therefor receiving the bulk of the business that is going. New York quotes 7 cents on Trust price and 6⅞ cents for outside interests. Conditions here are

## The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

**Montreal, Que., July 3, 1916.**—Satisfactory conditions continue to prevail throughout the industrial situation, continued optimism is apparent in many directions while domestic trade continues to resume its normal position. The general steel situation has now apparently attained the high water mark and the next move is expected to be to lower levels.

## Pig Iron

There is little to report in the pig iron situation. Steel making pig is very steady but foundry prices are easing up as shown by a general decline of 50 cents a ton on many of the current quotations.

## Steel

While production is not any less, the

buying tendency is practically at a standstill although foreign interests are showing a little anxiety over the situation in the States. The general feeling is that the top of the upward movement has been reached, and the question now appears to be, the length of time that the market will rest before a downward movement begins. No price changes are reported during the week. Owing to labor shortage it is reported that some cancellations have been made on bars, consumers being unable to use the quantity previously ordered. The market in sheets is quiet, but mills are very busy on special sheets. The wire rod demand is not brisk, but in event of a break with Mexico, the stoppage of export from the States would result in in-

unchanged, and prices are firm at 9 cents per pound.

**Antimony.**—Buyers are showing little interest in the situation and the market continues to weaken. New York prices are now 17½ cents, and a decline of 2 cents on the local market places the current quotation at 28 cents per pound.

**Aluminum.**—The demand for aluminum has decreased and prices are easier. New York prices have declined two cents and local dealers are asking 65 cents which is a decline of one cent over that of last week.

#### Machine Tools and Supplies

The situation in the machine tool industry is much the same, with the pressure on the manufacturers gradually being removed, and the possibilities of delivery becoming more normal. With the exception of the heavier equipment, and such small orders as are required for the maintenance of standard machines, the situation is gradually resuming a normal condition. The demand and inquiry for domestic tools is still good and the outlook is encouraging. Owing to the continued activity in munition plants the demand for supplies is still very great and accessories are still required in large numbers, with little relief in the way of prices, but much better deliveries on necessary supplies.

#### Scrap

Consumers are apparently still well supplied and the market is comparatively unchanged. Business is light in heavy melting steel and New York prices are a little weaker; quotations on old steel rails and R. R. wrought iron are also easier, but buying is light. Brass scrap is slightly stronger and also aluminum, but old lead and zinc have declined. While local dealers are fairly busy they are holding firm on price quotations.

**Toronto, Ont., July 4.**—The continuance of further orders for munitions to be made in Canada has been assured by the establishing of additional credits for the Imperial Government. The total amount of the new credit will probably be over \$50,000,000., the exact amount however, will be determined shortly by the Minister of Finance and a Committee of the Canadian Banker's Association. Previous credits have enabled the Imperial Munitions Board to distribute large orders for shells in Canada, with the result that over 300 plants are now busy producing munitions. This activity has been of the greatest benefit to the engineering industry as well as to the country generally. It is estimated that the Imperial Munitions Board is expending from twenty-five to thirty million dollars every month. This has only been made possible by establishing these

credits which not only benefit Canada industrially, but are also of the greatest assistance to the British Government in the control of the sterling exchange situation.

A statement recently issued by the Department of Trade and Commerce covering the returns for May, shows a heavy increase in exports of manufactured goods. These exports in May amounted to \$27,734,477 as compared with \$16,121,149 in the corresponding month last year. The imports also show a substantial increase. From an industrial standpoint, Canada is experiencing a wave of prosperity which will no doubt continue while the war lasts. During the period of re-adjustment after the war there will be reaction, but the effect of this can be offset to a great extent if manufacturers prepare for the change by developing their export business and also make determined effort to manufacture articles which hitherto have been imported, principally from enemy coun-

#### CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion \$100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

tries. Such a procedure would be of lasting benefit to the country generally.

#### Steel

The situation in the steel market is unchanged and prices have been maintained at last week's levels. The export business continues heavy but domestic demand is easier. An advance in lap-welded boiler tubes is expected in the near future, but prices are unchanged meantime. On locomotive and merchant tubes most makers have their output sold for practically the remainder of the year. The wrought iron pipe market is easier, the new demand being lighter. Many mills are filled up for four or five months on lapwelded sizes, but can make fairly prompt delivery on butt-weld pipe. The skelp situation is unchanged, the mills having their output sold up over the next three or four months. Prices of wire rods are a shade easier but smooth steel wire has advanced 15c and is now quoted at \$4.05 per 100 pounds. Cold-rolled shafting is easier but unchanged and deliveries are extending into three or four months.

The sheet market is strong but quiet, and quotations are unchanged. Blue

annealed sheets are in good demand and prices have an upward tendency. Advancing costs of sheet bars and labor are expected to have a stiffening influence on all grades of sheets. The continued decline in spelter has improved the situation in the galvanizing trade but prices of galvanized sheets are unchanged locally although the market is easier in the States.

In the United States market there is evidence that the export business is sustaining prices as the domestic demand has decreased. New enquiries from Europe for Bessemer pig iron, steel billets and shell steel are in large volume while the export demand for steel bars is also heavy. The grave situation between the United States and Mexico is affecting the steel trade because of the possibility of early Government buying of steel products and munitions. Prices of some products are easier although the market generally is firm. Plates have declined to 3.25c Pittsburgh, but steel bars are unchanged at 2.50c and shapes at 2.50c Pittsburgh. Wire rods have declined \$5 and are now being quoted at \$50 per ton Pittsburgh.

#### Scrap

The market for old materials continues weak and dull. Quotations however are unchanged although declines are looked for in lead, zinc and brass scrap.

#### Machine Tools

Further orders for munitions are assured following the further credit which is to be arranged for by the Minister of Finance and the committee of the Canadian Banker's Association. Probably \$50,000,000 will be placed at the disposal of the Imperial Munitions Board for expending on shells which will keep the munitions plants busy for a long period, and machine tools will be required. The machine tool business continues brisk, and further orders for lathes have been placed while others are pending. Deliveries are improving from makers in the States and indications point that the pressure on machine tool builders there is fast subsiding.

#### Supplies

Prices continue to advance on some machine shop supplies but the principal difficulty that dealers have to contend with is the scarcity of some lines, drop forgings and steel pulleys being particularly hard to obtain. Some of the advances which have gone into effect recently are as follows:—Canadian made chucks are now 5 per cent off list; American "Independent" chucks are list plus 30 per cent., and geared scroll chucks list plus 40 per cent.; Cushman 3-jaw chucks style 21-28, list plus 30 per cent.; Cushman "Hartford" drill chucks list plus 10 p.c. with shanks for

same and parts list plus 10 per cent. Malleable lathe dogs are now 45 p.c. off list. A new price list on "Stevens" drill vises and bench vises has been issued. A number of lines of saws are now quoted at 25 p.c. off list and include solid tooth and inserted tooth circular saws, shingle and heading saws, mitre and novelty saws, circular milling saws, narrow band saws and gang saws. Concave and grooving saws are 5 p.c., wide band saws 35 p.c., special milling saws net list and metal splitting saws 50 p.c. Skinner drill chucks, geared pattern, are now list plus 15 p.c. and standard pattern list plus 5 p.c. A new price list has been issued on adjustable wrenches which carries a discount of 20 p.c. J. H. Williams products, have advanced and include drop forged wrenches 25 p.c., "Vulcan" and "Agrippa" chain pipe wrenches 25 p.c.; "Vulcan" chain pipe vises 15 p.c.; clamps list plus 25 p.c.; and drop forged lathe dogs list plus 15 p.c. Makers of high-speed steel cutters have shaded their prices while high-speed tool steel has also a weaker tendency. Owing to the decline in pig lead, prices of lead sheets are lower.

#### Metals

The downward tendency in prices of practically all metals except aluminum is the principal feature of the week, while the demand for most metals continues light there is evidence that prices are gradually working down to a more normal level. Production and consumption are now more evenly balanced and a falling off in demand will thus tend to lower prices. The position of copper is rather different from the other metals owing to the enormous war consumption and it is hardly likely that prices will decline in the same proportion as lead, spelter or antimony. After the war the industrial demand for copper will be so heavy that the possibility of any pronounced decline in prices for many months seems remote.

**Copper.**—The market is firmer in London but weak and dull in New York. Further price concessions have been made by second hands to attract buyers, but producers continue to hold firm. The visible supply of copper continues to decrease and it is quite possible that the Allies will be in the market for good sized tonnages in the near future. In view of the fact that producers are sold up for three or four months ahead, there appears to be little possibility of any marked decline in prices. Local Quotations are lower and nominal at 30c per pound.

**Tin.**—The market is weaker and unsettled due to lack of interest on the part of consumers and a big increase in stocks. It is believed in some quarters that tin is cheap when compared with

other metals and that the market will recover in due course. Local quotations are lower and nominal at 46c per pound.

**Spelter.**—Quotations continue to decline and the whole spelter situation is unsatisfactory. Producers are lowering quotations in an effort to interest consumers but little buying has developed. Spelter has declined 1c locally and is now quoted at 15c per pound.

**Lead.**—The market is steady and unchanged with the "Trust" quoting 7c New York. The situation in the New York market is uncertain and indications point to a decline in prices unless the export demand is renewed. Lead is unchanged locally at 9c per pound.

**Antimony.**—Sellers are slowly reducing prices to get what little business is offering with the result that the market is weaker with prices lower. The local

#### ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

**International Purchasing Commission, India House, Kingsway, London, Eng.**

**French.**—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministère de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

**Russian.**—Col. N. Golejewski, Military Attaché, Room 904 Flat Iron Building, New York City.

market is dull and easier at 28c per pound, quotations being entirely nominal.

**Aluminum.**—The situation is unchanged but the market is stronger and quotations higher at 67c per pound.

#### SHIPPING FACILITIES FOR EXPORT TRADE

IN regard to the new service on the Pacific, there is no doubt that American trade has suffered much from want of transportation facilities since the withdrawal of the ships of the old line. It is quite clear that countries which possess ships of their own are in a better position to engage in trade with foreign countries than those who have to depend upon foreign bottoms to convey their overseas commerce. That the Pacific Coast trade of Canada with foreign ports has suffered for want of

shipping facilities, not only since the war began but for years before, has been freely stated. Observations made upon Canada's small trade with China would seem to bear out the truth of this statement. The rate of progress which the Japanese are making in the construction of ships, unless other countries soon make a start to do likewise, must ultimately place the Pacific carrying trade practically all in the hands of the Eastern nation.

It is of interest also to observe the class of vessels which Japan is constructing for this service. Fairly large steamers of 6,000 to 8,000 tons, not of great speed, but essentially freighters, and designed to handle rough and heavy cargo, such as timber, flour and machinery. The passenger accommodations on many of these ships are confined to intermediate and Asiatic travellers, and being comfortable and clean, if not luxurious, are well adapted to all the requirements of this service. It would seem that a line of intermediate ships of this class might find ample business in the Canadian trade with the Far East.

#### AGRICULTURAL MACHINERY NEEDED IN INDIA

THE agricultural machinery opening in India is the subject of the following article, in the Implement and Machinery Review. It will appeal more especially to the Canadian manufacturers of farm implements who are on the lookout for a channel of foreign export.

The enterprising implement and machinery manufacturer, who is on the qui vive for new avenues of trade, might with considerable advantage turn his attention to the East, and closely study the needs of our vast Indian Empire. Rich in historical associations, but lacking the material wealth which only industrial development can produce, this country offers almost a virgin field to engineers and machinery makers. India has so far only experienced a passing acquaintance with modern mechanical power for industrial pursuits, but she is awakening to the possibilities afforded, and step by step machinery will be introduced until, with the great increase in the wealth of the country, the demand for machinery will grow enormously. Already on a limited scale India is sharing in the general output of munitions, and this has prompted the thought that if she can successfully apply herself to this class of manufacturing, other trade is open to her.

The Provincial Department of Industries is being called upon to encourage the use of machinery, for it is regarded in responsible quarters that India's industrial progress will always be slow so long as the country is backward in mechanical engineering. Take the case

of agriculture, India's principal source of wealth. Owing to the primitive method of cultivation, a ryot performs one-twelfth of the work of an average English farm labourer, and the yield per acre is much smaller than on the average English farm, but in England mechanical plant is utilized to a degree undreamt of in our mighty Eastern Empire. In the year 1908, 34,450 engines with a horse-power of 213,525 were employed in Great Britain in the cultivation of 2,000,000 acres. It is contended that Indian agriculture offers even infinitely greater scope for machinery than does English agriculture, and as the area under cultivation is ten times larger than that of Great Britain, the machinery manufacturers who seek to cater for India's requirements must be impressed by the probable tremendous demand.

They must not lose sight of that fact, however, that competition in various types of engines and machines is restricted in India, owing to the lack of engineering resources in the country for

repair work, and also in view of the question of importing spare parts. One thing is abundantly clear, and that is that the popularity of agricultural machinery will increase when a sufficient number of millwrights' shops are established to perform repair work, and so remove the present worry and trouble. Beginnings have been made in this direction and also in securing competent mechanics. A concrete case of the saving qualities of machinery is given by the irrigation problem. Fully 33.3 per cent. of the land irrigated is watered from wells, and the labour of at least six million cattle is employed. Mechanical power would do all that is necessary in much less time, and at smaller expense. Only for the war, British manufacturers would have had on the market the small combined pump and motor combination the country requires, and a direct result of its installation would have been to increase the area cultivated. A good deal of missionary work is required to familiarize the Hindu cultivators with mechanical plant. The

obstacle of the small holdings will have to be overcome by co-operative ownership, whilst it will have to be made clear that only by the full use of machinery can its utmost benefit be derived. The Hindu seems to be content to employ machinery on a restricted scale, but fails to appreciate the gains to be derived from organized running.

**Can. Merchant Marine.**—The Dominion Government is investigating the possibilities of a Canadian merchant marine. It is thought that a resort will be made to bond guarantees, and subsidies may be granted to equalize the difference between the cost of construction between Great Britain and Canada. However, no definite policy has been arrived at. No doubt the first move will be to extend the Government freight carrying service between Halifax and Liverpool in conjunction with the Government-owned land service by the Intercolonial and National Transcontinental Railways.

## CANADIAN COMMERCIAL INTELLIGENCE SERVICE

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

# INDUSTRIAL <sup>AND</sup> CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

## Engineering

**Walland, Ont.**—The Welland Motor & Machine Co. will build a factory at a cost of \$3,500.

**Sunderland, Ont.**—T. Welsh is in the market for two 15-h.p., three-phase, 220-volt, 60-cycle squirrel-cage motors.

**Montreal, Que.**—The Canadian Tube & Iron Co. has commenced the erection of a building to cost \$3,000.

**Renfrew, Ont.**—The Renfrew Electric Mfg. Co. has commenced the erection of an addition to its factory to cost \$5,000.

**Toronto, Ont.**—The Bawden Machine Co., 163 Sterling road, will erect frame and galvanized iron storage bins, at a cost of \$2,000.

**Peace River, Alta.**—The Department of Public Works, Ottawa, contemplate the installation of an electric generating plant.

**Hamilton, Ont.**—The Oliver Chilled Plow Works will build an addition to its plant on Burlington Street at a cost of \$2,000.

**Toronto, Ont.**—The Flint Varnish & Color Works, Perth avenue, will erect four steel and concrete storage tanks at a cost of \$2,000.

**St. Catharines, Ont.**—The Packard Electric Co. are building an addition to their factory, 50 ft. x 145 ft., of steel and concrete construction.

**Stellarton, N.S.**—The Acadia Coal Co. contemplate installing an additional unit in their power plant. This will consist of a 3,000 k.w. steam turbine.

**Lindsay, Ont.**—The Westinghouse, Church & Kerr Co., New York, have the contract for the Government's new ammunition plant to be constructed here.

**Hull, Que.**—The Hull Iron & Steel Foundries is building an addition to its plant, 90 x 150 ft., at a cost of \$30,000. It will be used as a small castings department.

**Sarnia, Ont.**—A site has been selected at Point Edward for the stone cutting plant which will be established by George Oakley, of Toronto. The new company is capitalized at \$100,000, and will cut all the stone required for the Union Station at Toronto.

**The Ontario Steel Products Co.** is making extensions to its plants at Chat-

ham and Gananoque, Ont., to take care of increasing business. The company has been working at full capacity for a considerable time on its regular spring, axle and shovel business, and has recently closed contracts for springs, etc., with several automobile manufacturers.

## General Industrial

**Guelph, Ont.**—The Dominion Linens will build an extension to their factory here.

**Berlin, Ont.**—Fire did \$500 damage to Kreiner & Co.'s furniture factory on Sunday.

**Peterboro, Ont.**—A by-law to aid the Bonner-Worth Co., in the erection of a new factory was passed on June 27, by a majority of over 400. The capacity of the present plant has been trebled within the past three years.

**Canadian Plant Projected.**—The International Paper Co., has plans made for a 200 ton newsprint mill to be erected in Canada. It is officially stated that this mill will produce newsprint, round wood pulp and a surplus production of sulphite pulp, and that construction will be begun as soon as a building material can be contracted for to advantage.

## Municipal

**Guelph, Ont.**—The City Council are in the market for a 750 h.p. transformer.

**Montreal, Que.**—The Town Council of Pointe aux Trembles, near here, contemplate installing a waterworks system.

**Birchcliff, Ont.**—The ratepayers of this district have endorsed a scheme for installing a hydro-electric system here.

**Kingsville, Ont.**—The Town Council will submit a by-law on July 5 to authorize the expenditure of \$16,000 on waterworks improvements.

**Saskatoon, Sask.**—A by-law will be voted on by the ratepayers on July 26 for \$90,000, to provide for an incinerator and to purchase a site. The cost of the incinerator alone is estimated at \$30,000.

**Windsor, Ont.**—An important session of the Essex Border Public Utilities Commission was held at the City Hall here on June 28, and at its conclusion it

was announced that the commission had ratified the appointment of a Board of Engineers to prepare comprehensive plans for a joint sewage and water system for the six Canadian border municipalities. When the plans are perfected the ratepayers of Windsor, Walkerville, Sandwich East, Sandwich West, Ford and Ojibway, the municipalities affected, will be asked to vote on the project. The approximate cost of a new sewerage system for the border towns is estimated at between \$1,500,000 and \$2,000,000.

## Tenders

**Saskatoon, Sask.**—Tenders are being called until July 26 for a high pressure water main system.

**Victoria, B.C.**—W. Galt, city purchasing agent, is receiving bids for a quantity of supplies which are for sale, including brass goods, hose nipples, lead and iron unions, cocks, lead pipe, and valves, etc.

**Halifax, N.S.**—Tenders will be received until Wednesday, July, 19, 1916, for furnishing 2,800  $\frac{5}{8}$  in. meters and 300,  $\frac{3}{4}$  in., meters in accordance with the specification made by the City Engineer. Further particulars may be obtained from H. W. Johnston city engineer.

**Prince George, B.C.**—Tenders for power plant equipment for the City of Prince George, B.C., will be received at the office of the city clerk, up to July 8, 1916. Specifications and instructions may be obtained at the office of the city clerk, or at the office of the consulting engineers. DuCane, Dutcher & Co., Rogers Bldg., Vancouver, B.C.

**Welland, Ont.**—Tenders for repairs to the southerly end of elevator mooring dock at Port Colborne, Welland Canal, will be received until July 14. Specification and form of contract to be entered into can be seen at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the superintending engineer, St. Catharines, Ont.

**Toronto, Ont.**—Tenders for Examining Warehouse will be received until July 17. Plans, specification and form of contract can be seen and forms of tender obtained at the offices of Thos. A. Hastings. Clerk of Works, Postal

# The A. R. WILLIAMS Machinery Company Limited

**CANADA'S LEADING****MACHINERY HOUSE**

ST. JOHN

TORONTO

WINNIPEG

VANCOUVER

**W**E ARE SOLICITING YOUR INQUIRIES AND orders for every kind of machinery that is required in Machine Shops, Wood Working Factories, Saw Mills and Planing Mills.

**F**OR OVER FORTY YEARS we have been engaged in this business. Starting in a small way our organization has grown until it now stretches across the wide expanse of the Dominion with offices and warerooms at St. John, N.B.; Montreal; Toronto; Winnipeg, Man.; and Vancouver, B.C.

**O**UR CONNECTION is with the largest and most up-to-date manufacturers of wood and iron tools on this continent.

**O**UR POLICY is to sell only at manufacturers' prices to the users.

**O**UR ORGANIZATION is built on the ideal of "Efficient Service" to our customers and our success is evidenced by the growth of our business and the centres established at the most important points in this country.

**W**E NOW SEEK TO APPLY THIS IDEAL of "Efficient Service" to the export field, being well assured of the outcome.

*We can serve you. Write us.*

**The A. R. Williams Machinery Co., Limited**  
**64-66 FRONT STREET WEST, TORONTO**

Station "F," Yonge Street, Toronto, Ont., R. L. Deschamps, Central Post-office, Montreal, P.O., and at the Dept. of Public Works, Ottawa.

**Ottawa, Ont.**—Tenders will be received until July 10 for 163,500 lbs. of galvanized iron telegraph wire, delivered at Montreal, Que., or 128,500 lbs. of same delivered at Kamloops, B.C., and 35,000 lbs. delivered at Vancouver, B.C.; early dates of delivery desired. Specification and forms of tender can be obtained on application to the office of the General Superintendent of the Government Telegraph Service at the Department of Public Works, Ottawa; also at the office of J. T. Phelan, superintendent of Government Telegraphs at Vancouver, B.C.

**Steam Turbo Alternator, Etc.**—The corporation of Invercargill, New Zealand, is calling tenders for a steam turbo alternator, condensing plant and switchgear. The contract to be let is for the manufacture, supply, delivery and erection, duty, railage, and all other charges paid, including all labor in buildings and upon foundations constructed by the corporation of all plant and material required for a steam turbo alternator complete with necessary condenser, fittings, auxiliaries and all apparatus, whether specified or not particularly mentioned necessary for proper and efficient operation of the plant. Tenderers must state in what time they will guarantee to complete the whole of the contract, including all tests. Time to date from acceptance of tender. Such acceptance may be by letter, telegram or cable. Specifications and plans may be obtained by writing to the Commercial Intelligence Branch, Department of Trade and Commerce, Ottawa, referring to File A-1939.

## Contracts Awarded

**Port Arthur, Ont.**—The contract for the new 300,000 bushel elevator has been let to Barnet & McQueen.

**Fredericton, N.B.**—The Dominion Bridge Co., has been awarded the contract for the superstructure of the Aroostock Mouth bridge at \$33,318. They will erect the Jemsey bridge for \$33,094.

## Personal

**Captain Archibald Reid**, for many years Lloyd's surveyor at Montreal, has resigned.

**Charles L. Marble** has been appointed manager of the Wayne Oil Tank & Pump Co., of Woodstock, Ont.

**W. J. Alderson**, has been appointed Lloyd's engine and ship surveyor for the ports of Montreal and Quebec.

**E. R. Gray**, assistant city engineer of Hamilton, Ont., has been recommended by the Board of Control for the position of chief engineer, to succeed A. F. Macallum.

**Walter S. Barrows**, foreman of the plating department, the Canada Cycle Co., Toronto, and Supreme President of the American Electro-platers Society, is again back to business, following a long and trying sickness.

**Watson Griffin** has been appointed superintendent of the Commercial Intelligence Branch of the Department of Trade and Commerce. Mr. Griffin was until recently special trade agent for Canada to the British West Indies.

**J. C. Gwillim**, professor of mining engineering at Queen's University, Kingston, Ont., has been appointed an officer in the Canadian Engineers and will leave shortly for Valcartier, where he will assume his duties.

**J. McGregor**, superintending engineer of the Halifax Ocean Terminals, has obtained leave of absence from the railway department to go to the front. Mr. McGregor will be chief engineer of the railway construction battalion commanded by Col. J. W. Stewart, with the rank of Major.

**Captain Wm. Mathews**, master of the schooner, "General Laurie," of Lockeport, N.S. is to receive a silver souvenir from the King of Norway, in recognition of the services rendered the master and the crew of the Norwegian barque "Forth," of Sandefjord, lost on the 27th September, 1915.

**Robert Maitland Roy, C.E.**, manager and director the Hamilton Bridge Works, Hamilton, Ont., died on June 27, following an illness of about six months duration. Deceased was born at Stirling, Ont., on November 28, 1869, and had been manager of the Hamilton Bridge Works since 1908, and a director since 1913.

**Capt. Archibald Reid**, for many years Lloyd's surveyor at Montreal, has resigned. His place will be taken by **W. J. Anderson**, a shipping and engineering surveyor of Lloyd's, who will watch Montreal and Quebec ports. Captain Reid has combined the work of port warden and surveyor for years; now the work has become too heavy for one man to perform it, so the post has been divided.

**Captain Blanchard Henry**, commanding the transport Ionian, has been especially mentioned by the Admiralty

for work in the evacuation of the sick and wounded from the Gallipoli Peninsula. Captain Henry carried out responsible duties, say the Lords of the Admiralty, "with devotion, zeal, readiness, resource, and dispatch, never known to have been equalled." Captain Henry's home is Montreal, and he has seen thirty years service with the Allan line. He commanded a transport carrying some of the original Canadian contingent to England. He holds a medal for transporting troops during the South African War.

## Building Notes

**Toronto, Ont.**—The Northop & Lyman Co., will build a warehouse to cost about \$75,000.

**Toronto, Ont.**—The Separate School Board will erect two-storey brick school, on Broadway avenue, at a cost of \$24,000. They will also erect a two-storey brick school on 783 Bathurst street, at a cost of \$9,000.

## Woodworking

**Berlin, Ont.**—It is announced that the National Furniture Co. of this city, has been taken over by E. O. Weber, of the Waterloo Furniture Co.

**Windsor, Ont.**—Fire totally destroyed the lumber and planing mills of C. F. Smith at Harrow, near here, on June 24. The damage is placed at \$8,000.

## Trade Gossip

**Halifax, N.S.**—The head office of the Camaguay Electric Co. has been removed from here to Montreal.

**The Storey Pump & Equipment Co.**, Toronto, have been awarded a contract for pumps and filtration plant for Niagara-on-the-Lake, Ont.

**Campbell & Deyell** have closed their office in Schumacher, and in future will have all work attended to at the Cobalt works.

**The Roelofson Elevator Works**, of Galt, Ont., have been awarded a contract for an electric elevator by the Hample Paper Box Co., Brantford, Ont.

**The Zenith Coal & Steel Products**, of which G. D. Drummond, is president, and C. D. E. Wilson, secy.-treasurer, will deal in coal, coke and steel products. The capital stock is \$35,000 and the head office, Montreal.

# *Aikenhead's* THE DUMORE GRINDER

A Tool of Many Uses.

has become known as the most efficient Portable Grinder. Wherever there is grinding to be done, the DUMORE is necessary. With it you can do all kinds of grinding, longitudinal, cylindrical, internal grinding and other hard-to-get-at jobs. It is portable—Weighs only 17 lbs. Easily carried from one job to another.

The DUMORE does better work than the ordinary grinder, because it is better built. It is dynamically balanced. The motor and internal attachment are equipped with S. K. F. Ball Bearings.

No end play—No vibration. Absolutely perfect work assured.

**CUTS THE COST OF GRINDING OPERATIONS.**

**Canadian Machinery**  
*Classified Advertising Section*

**Montreal Metallurgical Association.**—The summer meetings of the Montreal Metallurgical Association are taking the form of evening visits, once a month, to the various plants about the city. The June visit was to the plant of the Canadian Steel Foundries at Point St. Charles and the July outing will take place on the evening of July 5 to the plant of the Dominion Glass Co.

**French Car Shipment.**—The first shipment of cars for the French Government, from the Eastern Car Co., plant, New Glasgow, has been made, we are informed. These cars are smaller than those made for the Russian Government. They are open gondola type, and each car is equipped with a small caboose on the end, which protects the trainmen from the weather.

**The Roelofson Machine & Tool Co.** has been organized at Galt, Ont., with E. C. Roelofson, formerly of Galt, who has been in Toronto for some years as president and general manager, and his brother, A. C. Roelofson, works manager. E. B. Roelofson, Galt, is vice-president. Work has been started on a factory 185 feet by 105 feet on Beverley street, and it is expected that the building will be completed by August.

**Consignment to South Africa.**—Official advice has been received from Mr. Egan, Canadian Trade Commissioner in South Africa, that consignments to order or through forwarding agents for Delagoa Bay will not be allowed to go through. Certain consignments for Delagoa Bay on the last steamers from Canada were landed at Durban. All consignments for Portuguese East Africa must name consignees or as it is sometimes called in South Africa destinations on bill of lading.

**New Mining Area.**—The largest mining district in Canada is to be made of the northern part of Manitoba, according to the announcement made here recently by Hon. Dr. Roche, Minister of the Interior. From the head of Lake Winnipeg to the Arctic seas, and from Hudson Bay to the boundary line between Manitoba and Saskatchewan, is the area decided upon. It approximates 200,000 square miles of territory, the headquarters of which will be located at The Pas, Man.

**Italy Purchases Old Steel Rails.**—Three thousand tons of worn-out steel rails recently constituted the cargo of a homeward-bound Italian steamer when it left its berth in the Delaware River. The old rails were no longer fit for service, and had been scrapped by one of the eastern transportation companies. Owing to the shortage of iron and steel

abroad, they were purchased by agents representing the Italian Government and will be melted down for use in the manufacture of munitions of war. To facilitate loading, the rails were cut in two on the dock with the aid of oxy-acetylene torches.

**Trade With Russia.**—In keeping with the policy outlined by Sir Thomas White to the Canadian Bankers recently advocating steps for developing trade with Russia, the Trade and Commerce Department in the past year has been making investigations and generally looking over the ground. C. F. Just, one of the Trade Commissioners, has interviewed Russian importers and has forwarded to the department numerous communications dealing with trade prospects. It has been decided to make Mr. Just trade representative in Russia permanently, while W. Wilgress, after several months' service in the department, has been assigned to a trade mission in Siberia. His headquarters will be at Omsk.

**The Canadian Electrical Association** held their annual meeting this year on board the Canada Steamship Lines steamer "Toronto." A large number of members took advantage of the opportunity of seeing the Thousand Islands, thus combining business and pleasure. The party left Toronto on the afternoon of June 21, going as far as Prescott, where the Montreal delegation joined the Ontario members. On the return trip the business of the association was transacted, a very successful outing terminating with the arrival of the steamer at Toronto early on Friday morning. The weather, although cool, was bright, and the trip was much enjoyed by all present. Much of the success of the meeting was due to Alan Sullivan, the secretary of the association, who was responsible for the arrangements of the trip.

## New Incorporations

**Toronto Opticians** has been incorporated at Toronto, with a capital of \$40,000, to carry on the business of manufacturing all kinds of optical goods. Incorporators: W. A. Lamport, H. M. Ferguson, and W. J. McCallum, all of Toronto.

**The Colonial Chemical Co.,** has been incorporated at Toronto with a capital of \$40,000 to manufacture nitrate of ammonia and all by-products thereof. Head office at Toronto. Incorporators are F. Regan, J. Callahan and W. Menton all of Toronto.

**The Atlantic Chemicals** has been incorporated at Toronto, with a capital of \$40,000, to manufacture nitrate of am-

monia and chemicals of all kinds. Head office to be situated at Toronto. Incorporators: F. Regan, J. Callahan, and W. Menton, all of Toronto.

**The Bras d'Or Coal Co.** has been incorporated at Ottawa, with a capital of \$45,000, to mine and deal in coal, coke, ironstone and other minerals. Head office to be situated at Montreal. Incorporators: H. A. Lovette, G. W. Cole, and B. F. Bowler, all of Montreal.

**Baldry, Yerburch & Hutchinson** has been incorporated at Toronto, with a capital of \$561,000, to carry on the business of engineers, contractors (dock, railroad and canal). Head office to be at St. Catharines, Ont. George Peterson, of St. Catharines, is the attorney.

**The Chapman Engine Mfg. Co.** has been incorporated at Ottawa, with a capital of \$250,000, to manufacture engines to be run by gasoline, kerosene and steam power, also electrical motors, machinery, tools, etc., at Dundas, Ont. Incorporators: G. W. Williams, F. E. Lennard, and J. D. Pennington, all of Dundas, Ont.

**The American Natural Gas & Gasoline Co.**, has been incorporated at Toronto with a capital of \$2,000,000 to refine and deal in natural and artificial gas, gasoline and peat for lighting and heating purposes. Head office at Toronto.

and the incorporators are E. R. Reynolds, a Van Dusen and John Mortimer all of Toronto.

**The Canadian Collapsible Tube Co.** has been incorporated at Ottawa, with a capital of \$100,000, to manufacture and deal in collapsible tubes of every type, shape and material, also in tin, lead and aluminum goods. Head office to be situated at Toronto. Incorporators: R. W. Hart, K. D. McKenzie, and W. W. Perry, all of Toronto.

## Marine

**Halifax, N.S.**—Work is being pushed hard on these terminals in order that three berths at least may be complete for shipping this autumn.

**St. Catharines, Ont.**—The steamer India owned by the Montreal Transportation Co., carried away the head gates of lock 12 in the Welland Canal on June 29.

**Ottawa, Ont.**—The Toronto Harbor Commission have deposited with the Public Works Department, for approval, plans of the bastion seawall to be built at the mouth of the Humber River.

**Sarnia, Ont.**—The wrecker "Favorite" of the Great Lakes Wrecking Co.,

along with the tug "Michigan", has succeeded in raising the overturned steamer "Chas. Price" sufficiently to enable them to bring her three miles closer to the mouth of the St. Clair River.

**Hull of Majestic Raised.**—The Reid Wrecking Co. has raised the hull of the steamer Majestic, of the Northern Navigation Co., which burned to the water's edge and then sank in shallow water in Sarnia Bay last Fall. An examination will be made of the hull, and if possible it may be rebuilt.

**Vessel in Halves Through Canal.**—On June 18, the fore part of the steamship "Harvey H. Brown" passed through the Lachine Canal, and was berthed in the Vickers Drydock to await the arrival of its aft complement, so that they might once more be united for a further life of usefulness at sea.

**International Mercantile Marine.**—The British Government has approved Harold A. Sanderson, E. C. Grenfell, of Grenfell, Morgan & Co., and Lord Pirrie, of Harland & Wolff, Belfast, as British nominees to the directorate of the reorganized International Mercantile Marine Co. Two British directors who will not appear on the new board are Charles F. Torray and J. Bruce Ismay. J. P. Morgan & Co., announce

## The Metals Coating Co. of Canada

Versailles Building, 90 James St.  
**MONTREAL, CANADA**

A machine gun making its ammunition from Reeled Wire, and coating objects by bombarding with minute plastic particles of metal. The Schoop method of Metallic deposition, any object and any size coated with a positive adhesive and homogeneous coating with any metal for any desired thickness.

Solves one of the greatest problems heretofore confronting the structural engineer, because it produces on iron or steel a permanent coating not susceptible to corrosion.

Carbons can be coated with copper, etc.

For full information write for booklet "D".

that J. P. Morgan and Charles Steel will represent them on the new board. Preferred stockholders are urging James N. Wallace to represent them, in addition to F. W. Scott, Harry Bronner, Charles H. Sabin, and either Albert Rathbone or George W. Davidson, and both, in the event of Mr. Wallace's refusal.

**Kingston, Ont.**—A new tug, built at the Davis drydock here for the Hudson's Bay Co., was successfully launched on June 22. The tug is 36 ft. long, 9 ft. 6 in. beam, and has a draught of 4 ft. 6 in. She is equipped with a 32 h.p. three-cylinder "Wolverine" engine, and will use either gasoline or kerosene.

**Canal Headgates Carried Away.**—The head gates of lock 12. Welland Canal, were carried away by the old wooden steamer India of the Montreal Transportation Company's line at 8.30 on the morning of June 29, causing \$5,000 damage to the canal and in addition inundating the surrounding country with water from the level above. Confusion of signals is given as the cause of the accident, the engines being started ahead at faster speed after Capt. Roach had endeavored to call for reverse. Several holes were punched in the bow of the steamer, and Lockmaster John Clark was carried over the bank by the water and received a ducking. Locktender Hilton of lock 11 was swept over the back into an adjoining field, landing against a barbed wire fence and had a narrow escape for his life.

**Standardized Ship Building.**—Details of the scheme for the building of standardized ships at Chepstow, Monmouth, England, are announced. The enterprise will have an initial capital of £100,000 sterling, which has already been subscribed. The stockholders are all large shipping companies, including the Peninsular & Oriental, the New Zealand Shipping Co., the Orient Steam Navigation, the Furness-Withy the Shire Line and the Federal Steam Navigation Co. No public issue of stock is contemplated. The head of the new enterprise is James Caird, President of Turnbull, Martin & Co., and director in numerous shipping and allied companies. A site has been obtained on the River Wye, and the plans provide for a plant capable of building ten large ships at the same time, all to be of a standard type of 8,500 tons. All the parts of the hulls and engines will be standardized.

Metal Novelties and Specialties.

195 Teraulay Street, Toronto, Can.

Nottingham, England. The principal features of this tool holder are dealt with in detail and the various sizes given.

**The Dearborn Chemical Co. of Canada,** Toronto, have issued a bulletin dealing with the treatment of boiler feed water. The composition of feed waters, the substances most commonly present, and their effect, are first described, followed by a description of the "Dearborn" method of treatment and their boiler preparations.

**Electric Motor Pump.**—A new bulletin issued by the Buckeye Pump & Mfg. Co., Columbus, Ohio, describes and illustrates the new "Buckeye" automatic electric motor pump. Two types are dealt with, for direct pressure and open tank service respectively. A specification is included covering the principal features of these outfits.

**The International High-Speed Steel Co.,** of New York, have issued an interesting book dealing with their high-speed steel tool and special alloy brands. Particulars are given as regards the class of work for which each brand of steel is recommended, with directions for treatment, together with heat and temper colors. Directions for hardening and tempering are included, and the sizes in which the various brand of steel are made. There are a number of useful tables giving the weight per foot of the various sections, with gauges, decimal equivalents, etc. The book contains 56 pages, is attractively gotten up, and is bound in substantial cloth covers.

**Hints on Steel** is the title of a very useful booklet, recently issued by Sanderson Bros. & Newbould, Sheffield, Eng., and being distributed in Canada by their Montreal agents, H. A. Drury Co. While the purpose is mainly to show the advantages of "SaBen" high-speed steel, many interesting and highly-instructive notes are given on the proper treatment and working of tool steel in general. The uses to which the various grades of carbon steel are best suited, the method of handling when forging, the most desirable temperature at which to forge and harden the tools, also a short chapter on annealing, are briefly dealt with. In addition to this, several rules and tables make the book valuable to users of high-speed and other steels.

**Coal and Ash Gates.**—The C. W. Hunt Co., Inc., West New Brighton, New York, have issued a new valve catalogue, No. 153, dealing with the "Hunt" coal and ash gates or valves for controlling the flow of bulk materials. The catalogue contains a complete description of standard types of valves, accompanied by illustrations showing the general features. Dimensions are given of those

## Saving or Wasting?

The manner in which you handle the drinking water problem in your plant may seem to be a small matter to you—but investigate. The results will be surprising.

The old-time faucet is costly. Running hour after hour, day after day, its ceaseless flow is costing you money, yet without any better service.

## Puro Saves 35%

A Puro Sanitary Drinking Fountain will cut that water bill 35%. We can prove that it has done that for others.

It will give every employee a safe, saner draught of bubbling water free from the contamination of the common drinking cup.

In a word, it is the only sanitary Drinking Fountain that is really safe, sanitary, simple, automatic in control, and easy to attach.

types which are most frequently used in power house and storage pocket design. Numerous cuts are included showing the application of these valves, and selected with the idea of assisting where there is any question as to the type best suited to requirements. The catalogue, 6 in. x 9 in., contains 28 pages, and copies may be obtained on application by those sufficiently interested.

**Recording Instruments.**—Instruments for recording carbon dioxide in flue gases are described in Bulletin 91, of the Bureau of Mines, Department of the Interior, J. F. Barkley and S. B. Flagg, authors. In explaining why the Bureau of Mines has issued a report of this character, the authors say: "In the past few years an awakened activity in power plant economies has resulted in a marked improvement in the equipment for generating and utilizing steam. Although the improvement in design and construction of steam-driven prime movers has been greater than that of the steam-generating equipment the economies obtained with the more efficient engines and turbines have stimulated interest and activity in eliminating unnecessary boiler and furnace losses. Much attention has been given to the boiler room in efforts to obtain proper combustion of the coal, because of the importance of the coal item in costs of power production. As evidence of this increasing interest may be cited the record of the development within the past few years of new apparatus for the analysis of flue gases. Many new forms of apparatus have appeared, including those for the determination of carbon dioxide, oxygen, and carbon monoxide, and others for indicating and for recording the content of carbon dioxide only, as carbon dioxide content is usually a good indicator for the control of furnace operation. Because of the large number of steam-power plants operated by the Federal Government and the number of carbon dioxide recorders used therein the Bureau of Mines undertook to collect information regarding the practical application of such recorders. Articles published from time to time concerning carbon dioxide recorders have been mostly descriptive, giving little reliable information as to the results that could be expected from the various types of instruments in ordinary practice, and most of the tests made have been of a laboratory nature. Tests of several different types of recorders were made under service and laboratory conditions in order to obtain needed information. The purpose of the Bureau of Mines in publishing the results is to show the factors which may affect the accuracy of a carbon dioxide recorder and the manner in which a recorder should be tested. Copies of this bulletin may be obtained free of charge by addressing the direct-

## Book Review

**Modern Starting, Lighting and Ignition Systems**, by Victor W. Page, nearly 400 pages, 5½ in. by 8 in., and over 250 illustrations with folding plates. Published by the Norman W. Henley Publishing Co., New York. Price \$1.50. This volume explains all forms of electrical ignition systems used on internal combustion engines of various types, and deals with the equipments of cars built in previous years as well as those in use this year. It also includes comprehensive instructions pertaining to the starting and lighting systems of automobiles. The book is essentially practical. While of considerable value to the mechanic, it has been written with special reference to the requirements of the non-technical reader, who may desire easily understood explanatory matter relating to all types of automobile ignition, starting and lighting systems. The aim of the author has been to present a book that can be understood even by those whose knowledge of electrical matters is limited. In order to help the reader who is deficient in this respect, elementary electrical principles are dealt with at length in chapter one, the succeeding chapters dealing with the various systems covering construction and operation. Chapter two describes different battery and coil ignition methods, while the following chapter deals with magneto ignition systems. Elementary electric starter principles are discussed fully in chapter four, and in chapter five typical starting and lighting systems are described in detail. Chapter six deals with starting system faults and their systematic location, while chapter seven is devoted to a description of miscellaneous electrical devices. The illustrations, which are very explanatory, are from specially-prepared engravings; in addition, there are some interesting folding plates. The book is bound in attractive and substantial cloth covers, and the reading matter is printed in clear type.

THE Petrograd International Commercial Bank and the Russo-Asiatic Bank have formed a financial syndicate to promote a company, with a capital of 25,000,000 roubles (£2,756,250), for the metallurgical development of the Altai district of Siberia. The Russian Government, it is said, will take up one-half of the shares. The application for the concession sets forth that the South Russian and Ural metallurgical works have reached the limit of their productive capacity, and that it is necessary to erect new factories.

# Subscriptions Invited From Friends Abroad

*Canadian Machinery and Manufacturing News* is published weekly. Representing, as it does, the industrial life and activities of Canada, it should prove of very considerable value to those who wish to buy Canadian products, and to those who may wish to sell in Canada.

As a technical journal it compares very favorably, we think, with any other high-class publication, and will be found to be well worth the subscription price, and more.

If you are favorably impressed with this number, we think you will find other issues equally interesting. *Canadian Machinery* contains from eighty to one hundred and twenty pages—fifty-two issues in the year. We invite subscriptions from our friends abroad, and attach a coupon for the sake of convenience.

20,000 LBS. 5/8 GALVANIZED STEEL GUY wire. We can offer this wire at very attractive prices. Winnipeg Machinery Exchange, Sutherland and Gladstone Sts., Winnipeg, Man. (25)

1-2-SPINDLE SHAPER. WOOD TOP. JOHN Ballantyne, Preston, make. used two months. 1 Dynamo, 45 lights. Toronto and Hamilton Electric Co. make. Used five months. Good as new. Box 195, Jordon, Ont. (R.T.F.)

WE HAVE FOR IMMEDIATE DELIVERY ten No. 9 Bardons & Oliver turret lathes; code word "Cedar"; 2 1/2" capacity; exceptional value; price moderate. J. R. Stone Tool & Supply Company, 24 Goebel Building, Detroit, Mich. (24)

FOR SALE--EXCELLENT PLANT FOR THE manufacture of electric passenger and freight elevators, patterns, drawings, blueprints. Special and ordinary machinery and parts. We are instructed to offer this entire plant at a fraction of the cost. If you are looking for a splendid manufacturing proposition, write for particulars of this one. Winnipeg Machinery Exchange, Sutherland and Gladstone Streets, Winnipeg, Man. (24)

## USED MACHINERY FOR SALE :-

1 2 X 24 JONES & LAMSON CONE DRIVEN turret lathe; complete with countershaft; 1 cut off slide, 3 tool holders, 1 12" Cushman 4-jaw universal chuck.

1 2 X 24 JONES & LAMSON CONE DRIVEN turret lathe; complete with countershaft; oil pump and pan; 1 cut off slide, 3 tool holders, 1 12" Cushman 4-jaw universal chuck.

1 2 X 24 JONES & LAMSON CONE DRIVEN turret lathe; complete with countershaft; 1 cut off slide, 3 boring tool holders, 1 12" Cushman 4-jaw universal chuck.

1 14" DAVIS PLAIN CONE DRIVEN TURRET lathe, with countershaft.

1 STEEL GAS OVEN WITH FUEL HEATING chamber and two racks, mercury thermometer, made by Brantford Oven & Rack Company; never been used.

TAYLOR-FORBES CO., LIMITED, GUELPH. (1)

## FOR SALE

Fox Monitor Lathe, 18" x 5' 6", 9-hole turret, cross feed, hollow spindle, 5-step cone; good as new. Plating dynamo, 6 volts, 250 amp.; used only a short time.

PENDRITH MACHINERY COMPANY  
970 Queen St. West, Toronto

## FOR SALE

FOR SALE--ELECTRIC PLANT--1 CORLISS engine, 16 x 30; boiler 72" x 14'; 1 dynamo, 1,100 V., 60 K.W. alternating current; 1 dynamo, 500 V., 30 K.W., direct current; transformer, watt meters, shafting, pulleys, belts. All in first-class condition. Sold complete or in part. C. Zudle, Exeter, Ont. (26)

FOR SALE - THREE HOLDEN-MORGAN threading millers; one arranged for nose threading; two for base threading. One base threader can be changed to 4.5, as it was reduced from this size. Also two Bertram wavers and groovers, and one Martin, all used for 3.3 shells. Canadian Linderman Co., Ltd., Woodstock, Ont. (27)

FOR SALE--5 CARLOADS MACHINERY steel, consisting of rounds from 1/4" to 5", squares, flats, angles and channels. Also tire sections. Slightly rusted through being outside. Will move this entire stock at great sacrifice in price to someone who can take delivery of entire quantity at once. This is an exceptional offer. Box 210, Canadian Machinery. (1)

FOR SALE--NEW HAVEN, 60-INCH SWING Standard Engine Lathe--triple geared, 15 ft. bed, hollow spindle, cuts threads 1 to 12. Compound rest, countershaft, steady rest, wrenches, etc. This tool is in excellent shape and owner offers special bargain. Particulars from Winnipeg Machinery Exchange, Sutherland and Gladstone Streets, Winnipeg, Man. (24)

FOR SALE--McDOUGALL ENGINE LATHE 20" swing, 10' bed, complete with 20" 4-jaw chuck, countershaft, steady rest, face plate, gears, etc. This tool, we understand, has never been used; has been lying crated for about 5 years. We are having it cleaned and offer a decided bargain for quick sale. Winnipeg Machinery Exchange, Sutherland and Gladstone Sts., Winnipeg. (3)

## SITUATIONS WANTED

MECHANICAL ENGINEER OPEN FOR position as shop engineer or superintendent; Technical graduate; broad experience in design, construction and production; have practical experience in forging and finishing large and small shells; have highest recommendation for ability to handle men efficiently. Box 265, Canadian Machinery. (25)

MECHANICAL AND ELECTRICAL ENGINEER, 18 years' experience, plant layout and maintenance; expert draftsman; wishes change. Box 207, Canadian Machinery. (26)

POSITION WANTED AS SALESMAN, agent, or traveler, for mechanical goods, or machinery, by Chief Engineer, (Marine), thoroughly reliable, of good education and appearance. Box 209, Canadian Machinery. (3)

## WANTED

Burned out Tungsten Lamps, late type, drawn wire, 25, 40, 60 and 100 Watts, 110 and 115 volts.

DOMINION TUNGSTEN  
LAMP FACTORY  
ST. CATHARINES, ONTARIO

## REPAIRING

ALL KINDS OF MACHINERY REPAIRED, rebuilt and installed. W. H. Sumbling Machinery Co., 643 Yonge Street, Toronto, Ont.

## WANTED

WANTED--ELECTRIC TRAVELLING Gantry crane, span about 57 ft., clearance 50 ft., overhanging at one end; load 15 tons. State full particulars and price. Thor Iron Works, Limited, Toronto, Ont. (27)

WANTED BERTRAM WAVING ATTACHMENT for 4.5 Shells, with or without Lathe. Also 18" or 20" turret lathe. Give full particulars and price. Bowes, Jamieson Limited. (R.T.F.)

WANTED -- BERTRAM WAVING ATTACHMENT for 4.5 shells, with or without lathe. Also 18" or 20" turret lathe. Give full particulars and price. Bowes, Jamieson, Limited, Hamilton, Ont. (rtf)

## For Sale Cheap

1-Box Girder Type Overhead Hand Power Crane, 48" 6" span, 5 tons capacity; complete, less the Hoist. This is a good Crane for Foundry, Boiler Shop, Storehouse, Stone Yard, etc.

1-12" Single "I" Beam Overhead Hand Power Crane, 30' 19" span, 3 tons capacity; complete, less the Hoist.

1-10" Single "I" Beam Overhead Hand Power Crane, 23' 0" span, 2 tons capacity; complete, less the Hoist.

1-Brantford (Gas) Bake Oven and 4 Racks.

1-No. 5 High-Speed Hammer.

1-30" Hercules Drill, made by Cincinnati Bickford Tool Co.

2-Baker Type Vises.

1-Linderman 2-Spindle Boring Machine.

1-24" Drill, Bertram Company.

1-26" Drill, London Machine Tool Company.

1-Bowser 40 Gal. Varnish or Oil Pump and Tank.

minence in the smaller sizes of shells.

The thread milling machines used in this plant are of the Holden-Morgan type, a portion of the installation being shown in Fig. 15, while Fig. 16 shows a single

locking devices insuring accurate duplication of the work on each succeeding shell.

The shell itself is accurately located in position by conical surfaces at each end, being inserted in the mandrel through the rear end, which is then

by means of a clamping nut which engages with an external thread on the central portion of the mandrel. A small swivelling crane is provided, from which the clamping gear is suspended when it is withdrawn from the mandrel, keeping it free from dirt and damage, and avoid-

FIG. 16. VIEW OF THREAD MILLER SHOWING CRANE FOR REMOVING BREECH BLOCK FROM BACK END OF SPINDLE.

machine from a different angle of view. The shell is carried in the interior of a large hollow spindle or mandrel mounted in the headstock, which is securely fastened to the bed. Back of the headstock is a belt pulley which transmits motion through a double worm reduction gear to the mandrel, causing it to revolve at a suitable speed. The milling hob is carried on the end of a belt-driven spindle mounted on a carriage gibbed to ways on the top of the bed. A cross slide enables the hob to be adjusted laterally as well as longitudinally, positive stops and

closed by a species of breech block provided with a tightening device which forces the rear cone against the shell and wedges it up against the front cone, thus insuring a concentric thread being cut by the hob. The hob is inclined slightly, so that it is perpendicular to the angle of the thread, the advance of the work to suit the lead of the thread being had

FIG. 18. VISE FOR HOLDING SHELLS WHILE INSERTING ADAPTERS.

FIG. 17. BATTERY OF AUTOMATIC MACHINES PERFORMING ROUGHING OPERATIONS ON ADAPTERS.

ing fatigue on the part of the operator.

The entire operation of milling is completed in one revolution, the hob being first of all fed into the proper depth, and then the shell revolved by lifting up the handle below the end of the mandrel which brings a worm into mesh with the gear, an automatic knockout stopping the feeds, while a stop is provided for resetting the mandrel when starting a fresh cut.

The nose thread is milled in a similar machine with a smaller hob, and with a higher speed of revolution for the shell because of the smaller diameter of the hole being threaded.

#### Cleaning and Inspecting

Before having the adapter inserted the shell is thoroughly cleaned for preliminary inspection. It is most important that this cleaning be properly performed, as after the adapter is inserted, access to the interior can only be had through the nose, and the varnishing of the interior is liable to be defective if the surface be not absolutely free from grit, dirt, and grease. The expense of using pure gasoline for the cleaning operation has been greatly reduced by

washing the shells in a bath of Mystic compound, followed after draining by a rinsing in gasoline.

The preliminary inspection consists of

two handlings of the shells and the necessary trucking in and out.

#### Adapter Machining

Having passed inspection and received

reasonable certainty of going home to its seating in the recess without binding unduly on the threads.

The machining of the adapters is done in Potter & Johnstone automatic machines, which hollow out the cupped face and rough turn the threaded diameter. subsequent operations including finish turning in suitable lathe fixtures, and drilling and tapping the driving holes, which latterly have the thread drilled out to size, as shown in drawing of shell on page 607 issue of June 29.

Considerable thought has been given to the question of whether or not the adapters could be driven home by machinery. Naturally the preliminary work has been done by hand, and the experience so obtained has been of considerable value in reaching a decision in the matter, and so far it has not been considered advisable to adopt any power method of adapter driving. The principal difficulty arises from the high degree of accuracy demanded in the various dimensions. Despite the accurate nature of the threading machines and hobs, the tough nature of the shell forging and the occasional occurrence of hard spots render the production of a perfect thread commercially impossible. Slight

FIG. 19. HYDRAULIC BANDING PRESS OF THE TIRE-SETTING TYPE.

gauging all diameters, lengths, depths, threads, and bevels, and is done by the plant inspectors, and also by the Government officials. The two inspections take place immediately after each other, and as the Government inspection must be done in the official enclosure, the shop bench is built on the outside of the room and the shells arranged to roll along, receiving a progressive inspection of the various features, at the end of which they pull up in front of a trapdoor in the partition, through which they can be rolled as required by the officials.

The trap door is provided with locks, as required by regulations, but when swung down in use it forms a continuation of the bench, and dispenses with

certain marks, the shells are ready to receive the adapters. These are machined to size within required limits, which permit of a slight amount of selection, so that each adapter may be inserted with a

FIG. 21. HAND TOOL FOR REFACING BEVEL SEATS ON NOSE OF SHELLS.

FIG. 20. VARNISHING TANK AND DRAINING RACKS, SHOWING METHOD OF SLINGING SHELLS.

variations in pitch or diameter and the great length of thread, i.e., 3 in., combine to make it extremely difficult to produce shells and adapters which will be interchangeable. Consequently both shells and adapters are threaded within close limits and matched as nearly as possible from stock, a careful operator being able to judge from experience if a shell wants easing on the thread to insure a safe drive home. The necessity for care in this respect will be appreciated when it is remembered that if forced too hard the adapter will very probably seize in the shell and damage the thread, so that even though the adapter be removed by cutting out, the shell thread will be defective, and the scrapping of 8-in. shells cannot be done with the same impunity as was once the case with shrapnel.

#### Adapter Assembling

In driving the adapter, the shell is inverted and clamped in a special vise,

FIG. 22. MARKING AND PAINTING DEPARTMENT.

as illustrated in Fig. 18. This is similar to an ordinary bench leg, but not so

Pettman's cement, as called for by specification, is used for making the joint, which is riveted up by hand. Riveting is another point where the superiority of machine over hand methods has been open to question. The thickness of metal to be spread out is approximately 1 in., and rapid blows from a comparatively light power hammer are not effective to a sufficient depth to insure the adapter flange being filled out metal to metal to the bottom of the recess. The use of heavy hand hammers, of about 10-lb.

weight, has been found satisfactory, and these are applied with the shell still held in the vise. The low height of this allows a man to walk around the work while hammering so as to produce regular results.

#### Facing Base and Adjusting Weight

The shell is now returned to the machines, where the base is faced off to the high limit, this work being done in lathes fitted with driving sleeves and expanding centres, as shown in Fig. 14. The radius on corner of base is also put on now, and the shell is weighed on a large

possibility of damage through shells being dropped too suddenly on the platform. Four lathes are engaged on this work—two Fairbanks, one McGregor Gourlay, and one Milwaukee. They are arranged two on each side of the aisle, with the scales in the centre so as to be equally accessible from each machine.

After being adjusted to weight, the shells pass to the banding press, which is operated by an independent belt-driven pump. The press is of the horizontal concentric type with radial cylinders, and is illustrated in Fig. 19, being built by the West Tire Setter Co. The copper driving weighs 4 lbs. when finished, and in the rough state is approximately 8 in. bore by 2 in. long and 5-16 thick.

In order to insure easy assembly and machining, the band is put on hot, being heated up to a dull red, which expands the band considerably, allowing it to slip over easily and at the same time an-

high. It has a step in front on which the shell rests, and a hinged clamp for

FIG. 25. TYPES OF LIFTING HOOKS AND SLINGS.

tightening in place. A long double end pin wrench with tube extension handles allows two men to pull on each end.

dial Toledo indicating scale, which is built into the floor, so that the shells may be rolled on and off, reducing the

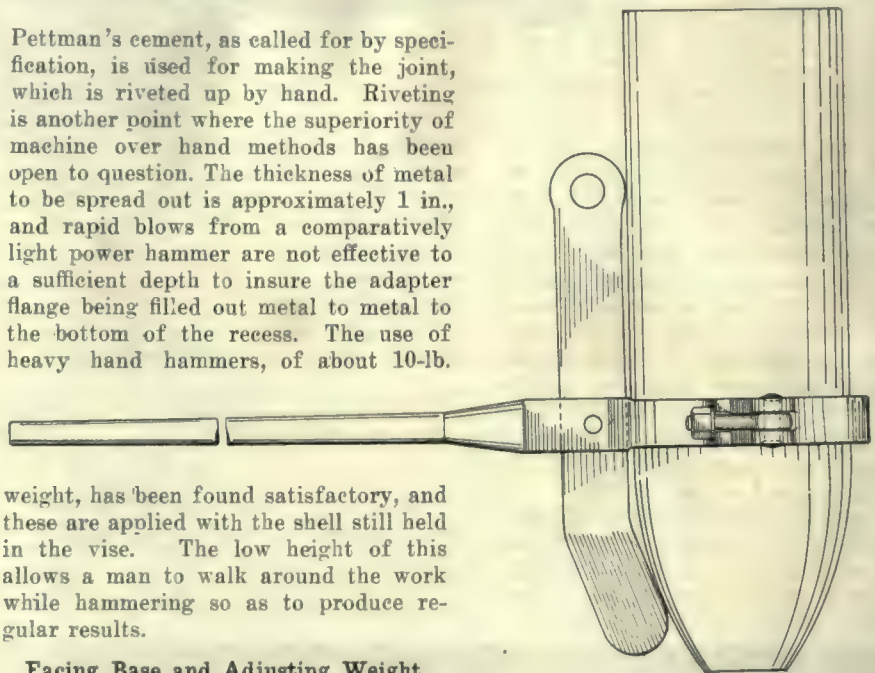

FIG. 24. CLAMP WITH HAND LEVER FOR LIFTING SHELL IN PRELIMINARY OPERATIONS.

neals it, the latter action being assisted by the rapid cooling when the dies come in contact with the hot copper.

Band turning is performed in plain lathes with universal chucks, the type of chuck employed on these machines being made by the Westcott Chuck Co.

Square revolving tool rests are used carrying one roughing tool and three profilers. The shell is gripped by the

base, so that the side thrust of the tool is taken by the front bearing of the spindle. The nose of the shell is conveniently supported by a pipe centre with very slight taper, which maintains the shell accurately in position without doing any damage to the thread.

#### Varnishing

The equipment for varnishing is of a simple nature, and with the use of unskilled labor has given satisfactory service. The shells are clamped around the body with a trunnion ring (see photo. Fig. 20) and hoisted by high speed chain blocks, which hold them under the swivelling discharge pipe of the Bowser measuring tank shown in the foreground, which measures accurately the amount of varnish or lacquer necessary to fill the shell. Immediately after filling, the shell is turned upside down and the varnish poured back into the tank. After a few seconds' draining, it is deposited in the rack behind, where it awaits the time when it will be put in a steel truck and run into gas-fired drying ovens.

The threads in the nose, which have been protected by bushings during the varnishing, are now thoroughly cleaned, and the bevel seating on the point of the nose is refaced by a hand-operated cutter, which removes any marks or damage, incidentally received during manufacture. A sketch of this tool is given in Fig. 21. A quill or hollow arbor is threaded at its lower end to fit the nose of shell. This threaded part is provided with expansion slots, so that after being screwed into the nose, it can be expanded tightly in place by an expander bolt, which is pulled up by a nut at the top end of the arbor (see sketch), the lower end or head of the bolt being tapered to fit the inside of the slotted part. This fixes the arbor firmly in position and true with the thread, forming a suitable support for the facing cutter which is formed of a sleeve with cutting teeth on its lower end, shaped to the correct angle of bevel. In operation, the cutter is pulled around by the two handles shown, and is fed by a collar which fits on a threaded portion of the arbor, a thrust washer being placed between the cutter and the collar. The device is simple and efficient, and provides a welcome means of rapidly removing disfigurements, which can hardly be avoided in handling, but which prevent the shell being accepted in spite of their seemingly slight nature.

#### Marking and Painting

The shell now receives final inspection before being marked and painted, both of which operations are done in the painting department, Fig. 22. To the right of the picture can be seen a heavy type Brown Boggs marking machine, which has proven very efficient on this work, uniformity of results, speed of

operation, and freedom from die breakage being features of its service.

The painting machine occupies one side of the room, being situated under the windows in Fig. 22. The machine consists of a strong timber framework, with two shafts running along the top, the driving pulleys being next the marking machine. A series of bevel wheels drives a number of vertical spindles from which the shells are suspended, threaded couplings fitting in the nose. In placing the shells in position, they are put on an elevating truck platform and run under the spindles, being lifted up by the elevating mechanism, so that a coupling pin can be slipped through, leaving the shell hanging. With the shells revolving, the application of the paint is a simple matter, the drying being assisted by the motion of the shells in the air, after which the shells are ready for shipping in individual boxes.

#### Handling Devices

Much of the success of work of this nature is due to the efficiency of the handling tackle. Where possible the shells are handled by Yale high-speed chain blocks suspended from trolleys on light I beams. In some of the illustrations there can be seen a runway or bench which occupies the centre of the aisles and allows the shells to be rolled from one group of machines to the next group, avoiding the use of trucks with their loading and unloading, and maintaining a continuous stream of work progressing forward. Fig. 23 shows a bench vise for holding the shell while being re-seated, the action being obvious from the sketch. Fig. 24 shows a special handled clamp for use with chain blocks in placing the shell nose down in operation 3; and Fig. 25 shows different methods of holding the shell at various stages, the centre being for cutting off machine, the right for inside boring and profiling, and the left for placing the shell with band on, in the marking machine.

#### DRILL WASTAGE

A REFORM which undoubtedly calls for prompt enforcement at the present moment is that relating to wastage in drilling, says Page's Weekly. In many engineering shops, especially those engaged on war work, the speeding up of drills has frequently led to a speeding down of output, simply because under the pressure of new conditions the well-established principles of working are frequently exceeded. Sometimes the result is disastrous in keeping back a host of allied operations which could have gone forward to completion at a reasonable speed: again, at all times the result is inconvenience and delay.

#### Drill Grinding

Added to this trouble is the supplying of drills wrongly or badly ground. Com-

plaints have been made regarding the cutting edges of twist drills. As the two cutting edges cannot meet at the centre, a non-cutting portion occurs, which ought to be thinned down more effectively than it is in some of the samples which have come under our notice. Unless this thinning down is accomplished according to a proper scale, and not according to some loose notions, the drill is not likely to prove entirely efficient, and it may break at the first onset. The scrap heap furnishes an eloquent proof of wasted drill power, and there is the further waste of power in the great addition of pressure needed to feed a drill which is not correctly thinned.

#### Durability Feature

Some other important considerations arise. Dealing with the subject of drills generally there are advocates of a greater clearance, angle than that usually given by a drill maker, the reasons assigned being that the greater clearance causes the metal to cut freer, and materially adds to the depth which can be drilled between the grindings. In this connection practical men have noted that the depth of the hole drilled has a very marked effect on the durability of the tool. The deeper the hole the oftener must the drill be ground because the lubricant cannot reach the drill point as freely as it should and also because hot chips lie against the tool, the body of which is thereby prevented from carrying away the heat generated at the point.

#### Simplified Data Required

All the reforms needed in the use of drills or other machine tools can be accomplished without an ostentatious parade of algebraic formulae. If we had less of the latter and more of plain English, the average engineer would be able to test in practice the information which is now frequently hidden from him in a mass of symbols. The ultimate test of every formula is the capacity for working it on a commercial basis as a part of a workman's routine. Nothing else appeals to a man who has to conduct his business for the purpose of gain. Much needless difference of opinion exists among machine tool owners and workers regarding workshop practice, chiefly because the results of experience have not been compiled in readily available form or because it has not been stated in a form understandable by plain man. Other branches of engineering appear to be more fortunate in that respect, for they enjoy fully correlated information. Hence occurs a great deal of the scrapping and wastage in machine tool shops, and the passing on of the trouble from one manufacturer to another until we are again confronted by all the old questions of standardisation.

### ZINC DEPOSITS NEAR OTTAWA

NEW and valuable deposits of Gatineau zinc have it is reported been discovered by a mining engineer, J. D. McFarlane, and a prospector, Dennis Callahan, formerly of Haileybury, in the vicinity of Burbidge station, which is about 72 miles from Ottawa. The discovery is of special interest in connection with the use of zinc in munitions manufacture.

Callahan made a discovery last fall which attracted much attention, and McFarlane was called to investigate. The deposits looked good and men have been working in the vicinity since. This spring, however, they have made what is claimed to be much more valuable discoveries north of the limestone area in which they were first prospecting. They have trenched across the ore vein at intervals of 1,400 feet, showing ore in places from six to fifteen feet. Mr. McFarlane, states that the deposits are rich, and that the mineral is much better than that found previously.

### THIRTY YEARS C.P.R. PROGRESS

THE C.P.R. held no celebration of its 30th anniversary on the 28th of June, but it published some very interesting facts and figures under the title "Thirty Years of Progress."

In 1886, the mileage of the company was 4,651 miles; now it is about 18,000—if all the companies which it controls, be considered. The gross earnings of the company in the initial year were \$10,081,000, but at present \$100,000,000 has been greatly exceeded. In 1886 the company possessed no steamships, except three on the Great Lakes. Now it has an aggregation under another name which is one of the strongest fleets in the world; and in addition the company operates fleets of speedy and luxurious vessels on the Bay of Fundy, the Great Lakes, the Kootenay, Arrow and Okanagan Lakes and on the British Columbia coast.

A comparison of the equipment possessed by the Canadian Pacific Railway at the close of 1886 and at the end of the last fiscal year (June 30, 1915), is interesting, and is as follows:

	1886	1915
Locomotives .....	372	2,255
First and second class passenger cars, baggage cars and colonist sleeping cars .....	304	2,182
First class sleeping and dining cars .....	47	502
Parlor cars, official and paymaster cars .....	27	97
Freight and cattle cars (all kinds) .....	8,253	87,504
Conductors' vans .....	178	1,424
Board, tool and auxiliary cars and steam shovels	71	6,467

The C.P.R. opened up the West, mak-

ing the towns and cities possible. Thirty years ago the prairies were a vast wilderness. To-day they are largely occupied with a prosperous and contented people. The company performs not only a national, but an Imperial service by linking up the various component parts of the Empire.

Such is what the company, not modestly, says of itself, but it might have gone much farther, for there is scarcely an activity in the West to-day that the C.P.R. has not been instrumental in setting agoing. Its penetration of the West gave the latter the first value it possessed, while its encouragement, all the way, of the settlers, to engage in other forms of activity and enterprise, in addition to wheat growing, made possible the manifold Western energies as we see those expressed to-day alike in agriculture and manufactures.

### BRITISH INDIA LEGISLATES AGAINST ENEMY TRADERS

A SPECIAL despatch from Simla says: that the Government of India have promulgated an ordinance dealing with the liquidation of hostile firms and the property of hostile persons; this brings the legislation of India into closer accord with the present state of the English law. The British Trading with the Enemy Act of 1916 enables action to be taken in the case of firms whose business, by reason of enemy nationality or association, is carried on wholly and with certainty for the benefit of enemy subjects. It also gives power to the Board of Trade to abrogate contracts or transfer power, which, it is believed, has for obvious reasons been very sparingly exercised. It also enables a company containing enemy elements to purge itself thereof with assistance of a custodian, who may permit British shareholders to put out enemy shareholders, depositing the price so paid with the custodian.

The ordinance follows closely the English Act with such modifications as local circumstances require. It will enable the Government to wind up hostile business much on the lines of the Indian Companies and Insolvency Acts, the distribution of assets so realized being subject to special rules. The liquidator will have power to give good title to purchasers of the good-will of hostile businesses and to immovable property held by them.

The new procedure represents a considerable advance from that hitherto adopted, in that the initiative for liquidation will come from the liquidator and will not be left nominally with the firm itself. It will also enable hostile businesses to be dealt with and to be completely extinguished, thereby prevent-

ing any chance of their recovering from the state of suspended animation and resuming business after the conclusion of peace.

### NEW BRITISH TRADE ORGANIZATION

AN important movement for the organization of British industry is represented by the United British Industries Association now in course of formation. The membership already includes fifty of the leading industrial concerns of the United Kingdom with an aggregate capital of \$250,000,000. An additional fifty members will be necessary before the Association deems itself formed. The entrance fee is \$5,000, so that the association will start its propaganda with a fund of \$500,000. The objects of the association were stated at a preliminary meeting to include:—

1.—Among other things, the war has shown us that foreign control of raw materials is as serious a danger to British industry as foreign attempts to capture our markets at home and abroad. After the war, the political world will be occupied with such questions as our Dominions' trade, the trade with the Allies, protection against German trade, the relations between capital and labour, new methods of taxation, and the solution of any unemployment problem that may arise; hence the necessity of some central and representative organization to deal appropriately with both political and commercial questions, so far as they may affect industry and trade.

2.—To command the attention of the Government when framing industrial legislation. At present, the trade unions are consulted, but there is no organization representing the business man to which any serious attention is paid.

3.—To deal with labour on comprehensive lines. The trade unions have adopted the principle of collective bargaining, and the employers of the country must have an organization big enough to make terms with labour—terms by which we may succeed in bringing about understanding and co-operation.

4.—To bring about organized efforts for the furtherance of British trade interests in foreign and colonial markets.

Austrian locomotive manufacturers are reported as unable to execute promptly the orders received from the government, because of lack of labor. A recent government order for 150 locomotives to be delivered in 1915 has been only partially filled, so that an additional order for 129 for delivery before July 1, 1916, is not to be negotiated unless the other order is filled at once.

## VALUE OF BELT TIGHTENERS

By N. G. Near

WITH reference to the extracts from the report by Professor W. W. Bird and Francis Roys, (page 619, Canadian Machinery), it might be well to point out the fact that these tests were made on belts that had not been waterproofed. Humidity does not affect a waterproofed belt to any appreciable extent, if at all.

I do not find any reference to the omission of this important point in the report of the above gentlemen, and therefore think it should be added, otherwise erroneous conclusions might be drawn. Readers are liable to think that leather belts are subject to change with humidity, but such is not the case as has been proved time and again with waterproofed belts. With a properly waterproofed belt, slipping does not occur when humidity increases. Of course, should humidity increase to such an extent that the pulley would become wet, the water on the pulley might serve as a lubricant and slipping would occur, but that would be a very extreme case and is seldom experienced in practice with belts used indoors.

Another point missed in the above report is the advantage of pliability with waterproofing which permits the belts to be run slack. High initial tensions become unnecessary. In that case, then, there is seldom any need for belt tighteners except on vertical or overpull belts. In fact, I wouldn't call them belt tighteners at all. I would prefer to call them "idlers" because the function of an idler should be principally to increase the arc of belt contact to a maximum rather than to "tighten" the belt. Arc of contact, with a good reliable belt, is more important than tension as can easily be proved by taking a "hitch" around a pulley with a pliable belt, and then with a stiff, dry belt. The pliable belt will hold, but the stiff dry belt will slip.

## TAPPER AND RECONSTRUCTED DRILL

By D. A. H.

IN the manufacture of some rifle attachments, large numbers of rods and brass and steel tubes were to be threaded and large numbers of  $\frac{1}{8}$  in. holes were to be tapped in  $\frac{1}{8}$  in. steel plates. This work had been done on a sensitive drill fitted with an Errington tapping

attachment, and would still be so done but for the pressure of other work necessitating the use of the drills.

It was decided to buy or make over some odd machine and jig parts that were available. We found on hand a cast-

ranged so that a length of 3 in. can be threaded.

The same pressure of work located the weak spot in a light drill press of the familiar type shown in the second photo. The drive was by belt from the cone pulley shaft up and over two idler pulleys at the rear top, and around the pulley on the spindle, and was as weak as many such drives are when forced a bit.

A change was made to gear and change drive by making a couple of bearing brackets and using a pair of bevel gears at the lower end, using a  $\frac{3}{4}$ -in. vertical shaft with sprocket on top, and putting a sprocket in

place of the pulley on the spindle. A diamond roller chain formed the final drive. While this drive was a little noisier than the belt, it hasn't slipped yet, and has required no taking up—but what is more to the point, the machine will now do double its former production.

TAPPER AND RECONSTRUCTED DRILL.

ing suitable for a base, a 54 in. length of  $3\frac{1}{2}$  in. pipe with one flange, a pair of pulleys, and a finished bracket of exactly the right shape for the table, faced on top and bored and split through the hub. It took but little consideration to see that the flange could be bolted to the base, the pipe turned off and the table applied. Then, with the Errington tapper, to give the reverse movement and the friction drive to the tap, there was little else to produce other than a "head" containing the bearings for two shafts at right angles, a hand feed, and to get the bevel gears.

How the machine looked when finished is shown by the photo. It will be seen that the vertical spindle sets close to the column — as close as the tapper itself will permit. This was done on account of the nature of the work primarily, but it also made for rigidity and compactness. The end of the spindle is threaded and set directly into the body of the tapper. Since put up, the machine has cut upwards of a hundred thousand threads ranging from a  $\frac{3}{8}$  in. buttress thread in cast iron to a No. 5 tap blind hole in steel. It is shown cutting a thread on the outside of 11-32 in. brass tubing. For outside work, a die holder is substituted for the chuck and ar-

## FOOLING THE ELEVATOR

By J. H. R.

HOW many of us have escaped the experience of that qualmish sensation at the sudden starting or stopping of a high-speed electric elevator? Very few; yet it is quite possible to take a trip on one of these perpendicular tramcars without being effected by this disagreeable feeling. The cause of the annoyance is the inability of the various organs of the body to attain the momentum of the elevator in the same period of time. Owing to the delicate construction of the human system, and the elastic manner in which many of the internal organs are supported, it is very difficult for some of them, more especially the stomach, to respond to any rapid or abrupt movement of the outward or more rigid portions of the body. When a person is traveling on a street car, any sudden action of the car will have the tend-

ency to throw the body in the opposite direction, unless by instinct or intention the body is set for the coming movement. However, in the case of the elevator, it would appear that the vertical movement of the body in unison with that of the car offers no opportunity of freeing one from this objectionable sensation; yet it is not only possible to overcome this feeling, but much easier to "fool the elevator" than the tram car.

If when stepping upon an elevator, and just previous to the starting or stopping, the entire body is lifted slightly, by raising the heels from the floor, or the knees are bent a little forward, (weak-kneed) sufficient spring is provided to allow for the sudden movement in either direction. By this procedure the internal members of the body will more readily adjust themselves to any abrupt action of the moving elevator.

### TO REMOVE A BROKEN STUD

By James E. Noble

SOME men drill a hole in a broken stud and proceed to drive a square drift, or piece of steel, into the hole and with a wrench endeavor to twist out the stud, more often than not they fail as such a proceeding will invariably press the bolt threads in tighter than ever.

One successful method to remove a broken stud is to drill a hole in the stud, then take a square piece of machine steel which will fit the drilled hole snugly, heat one end and hammer out the corners about 1-16 inch full, as at A A' A'', Fig. 1. Sharpen these cor-

FIG. 1. AID TO BROKEN STUD REMOVAL

ners with a smooth file and then temper the piece and draw it to a blue all over, now drive this tool into the hole in the stud, and the ends A, etc., will cut four grooves the depth of the hole. Next take a piece of tempered square steel 5-34 inch greater in diameter than the first piece, force it into the grooves and turn out the stud. It will be a stubborn bolt indeed which this will not remove.

Using a left hand tap to remove a right hand bolt has been suggested, also using a left hand drill has been recommended but neither method is in the same class for effectiveness as the foregoing.

### AN INTERESTING SHIPBUILDING TEST

By A. J. Campbell.

THE Nova Scotia Steel & Coal Co. are making a test of the cost of building steel ships on the Atlantic seaboard. On a site by the East River, at New Glasgow, immediately to the rear of the Eastern Car Works—a subsidiary concern of "Scotia"—the keel is being laid of a ship of 2,000 tons deadweight capacity. The craft will be 220 feet long, with beam 35 feet and a moulded depth of 20 feet. The boat will be built to Lloyd's classification, and with all the scantlings 10 per cent. in excess of requirements.

A 1,000 shaft horse-power DeLaval steam turbine is being specially constructed for this vessel, it being geared to the propeller shaft through two sets of gearing. This will be the first boat built in Canada to be equipped with a geared turbine. The equipment will also be unique in regard to the auxiliaries. A rotary air pump and a centrifugal circulating pump will be driven by a single engine. The stem, stern post and rudder forgings, propeller shafting, propeller and all fittings will be made by the company's New Glasgow plant. Frames, floor plates, and the bulk of the other construction material will also be furnished by the latter.

#### Permanence of the Enterprise

When this ship is completed, it will be fairly well determined what Government assistance, if any, will be necessary in order to make the industry a permanent one. It is hoped, however, that the experiment will prove the amount of this assistance to be not beyond the ability of the Government to grant. It must be remembered that the Nova Scotia Steel & Coal Co. have not definitely settled on a policy of shipbuilding. They have decided to build one ship and they hope to build many; but they are not going to say positively what will be done until they find out what this first ship will cost. It would seem probable that the cost will be higher than the normal cost of construction in England, owing to the higher price of labor. It may be, however, that the discrepancy between the cost of construction in this country and the cost in the Old Country is perhaps more apparent than real. Some well-informed observers declare that this difference is not nearly so great as the Canadian public have been led to believe. It is pointed out that while labor costs are less in the Old Country, labor results are also less. Thus, it may be found that what was supposed to be a 25 per cent. difference in favor of the British yards will be reduced to possibly 10 per cent. Better service largely counter-balances cheaper work. The New Glasgow test will prove what this argument is worth.

Certainly the location selected for this test possesses many advantages. It has been said more than once that if shipbuilding cannot be carried on profitably at New Glasgow it cannot be done anywhere in Canada. The reason given is that there are few places where so many economies in carrying on the undertaking can be effected. The site owned by the company is practically free. A portion of "Scotia" staff will carry on the business organization. Much of the necessary machinery which a new company would have to buy is already installed either in the steel works or the car works; indeed numbers of machines, useful for ship-building purposes are installed there which the ordinary yard could not well afford to purchase. Moreover there is a marked disposition on the part of workmen at New Glasgow to co-operate. The obstinacy of the unions in England is one of the handicaps of the British shipbuilder. The Nova Scotia Steel & Coal Company are large owners and charterers of tonnage; they operate a considerable fleet at the present time, and when this ship is finished, if there be no customer in sight, they can use her as a collier themselves.

#### Factors Towards Success

Colonel Cantley was asked the other day what he considered was necessary to make this ship-building project a success. He replied:

(1)—Government assistance; perhaps not very much, but some.

(2)—The hearty co-operation of the workmen; it must be assured against onerous labor legislation.

(3)—Good shipping laws. Some of the laws enacted by the United States have handicapped the operation of American shipping very seriously. For example, on an American ship of a certain size, the navigation laws call for a crew of 32, whereas on an English ship of the same size only 27 men are required. Such legislation as this, in addition to the higher scale of wages, makes it difficult for the American ship to compete in the open market in normal times.

(4)—Lower insurance rates, and also the inspection and registration of Canadian ships made easier for their owners. With regard to insurance, it is a fact that the Norwegians are insuring their fleet at about half the price our vessels are paying at the present time.

It will be admitted that there is logic in a plea for assistance for steel ship building. At the very least an amount equal to the duty imposed on the material that would enter into Canadian built ships should be returned to the builder, and since we give direct aid to the developing of our land transportation, why not do likewise to encourage the development of our own ocean trans-

portation? It is expected that the launching of this test craft will take place late this autumn.

### EXAMPLE OF WOMEN WORKERS

I AM acquainted with certain women who are working in munition factories and who only after a short experience of a technical school are turning out from lathes 2 per cent. more work of precisely the same character than skilled men are doing working on the same lathes one hour longer, says a London Times correspondent.

Such cases are not at all rare, and something ought to be done to induce the British workman to do the right thing by his country and by himself. It seems to me that the poison of limiting production so largely preached has entered very deeply into the constitution of the men, and in spite of its being war time they seem unable to free themselves these fetters.

### The Coming Industrial War

After the war victory in the industrial race will be to the country that can produce the most and the best from machinery, and if only British working men could be taught a more sound political economy so that they could understand that it was not only to the disadvantage of their country, but to the disadvantage of themselves and every one concerned to limit the natural output of a lathe or any other kind of machine, it would help very largely to hold our own in the future.

The trouble is that the great majority of men do not realize the necessity of giving value for the wages that they receive. This is not only dishonest; it is stupid, and steps ought to be taken to show how dishonest and how stupid it is. There are amongst the workmen a fair number who are perfectly willing to do a fair day's work and to get a fair amount out of the machines that they control.

### Physically Powerful Leaders an Asset

I know a case of an engineer who had retired previous to the war, who came back on its outbreak and started working in a large factory as an ordinary skilled mechanic. He did not strain himself, but simply kept steadily at work. Every kind of pressure was brought to bear upon him to bring his output down, as it was about 40 per cent. in excess of the average produced in his shop. He was a strong man mentally and physically, and in spite of being assaulted—when he laid out two men with a spanner—he continued his course. The good men in the shop eventually followed his example, and

in the end that factory produced on an average 30 per cent. more per day than they did previous to this man's example. He was then asked to go on the night shift, which he readily did, and in course of time produced the same result there.

This goes to show that the better class and the more willing amongst the men only require a leader, but the fact is the lazy and the incompetent are as a rule the loudest and the most turbulent, and they gain their ends over the better ones by means which can easily be understood. I am certain if the men would work honestly that an eight hour day would be infinitely more productive than a nine or a ten hour day under the restrictive action of the unions. The men could earn as much money and perhaps more, and the employer himself be better off. Surely it should be possible to so preach the doctrine of honesty and sound political economy that men should see the error of their ways and amend them. The example of women workers must be productive of great help in this direction.

### FORMING STEEL HEADS OF H.E. SHELLS

IN machining steel heads of high explosive shells from 4.5 in. to 6 in. inclusive, material in the form of blanks or forgings is used, the work being done on a

FORMING STEEL HEADS OF HIGH EXPLOSIVE SHELLS.

Herbert, Coventry, England, No. 4, Capstan lathe with two operations.

The forming of the external radius is done at the second operation, the work being held by the threaded part in a special chuck. This radius has to be finished subsequently on another machine when the head and body are assembled, so that the curve may be continuous. On the No. 4 Capstan lathe, the forming is usually done with a broad form tool carried in a suitable tool post on the back of the cross slide. When blanks are used, a considerable amount of metal has to be removed, which makes the forming rather a laborious opera-

tion, especially as hand feed must necessarily be used.

The accompanying illustration shows a new design of form tool holder which takes advantage of the automatic feed provided on the Capstan slide. The action of the tool is a combined turning and shaving cut, as it is fed to the work in a direction at right angles to that in which a cross slide form tool would be fed. The holder itself consists of a cast-iron bracket bolted to the capstan and provided with a central hole in which is clamped a revolving steady peg to suit the hole in the work. The form tool is a dovetail blade of high speed steel fitting in a slot in the holder and clamped by a pad bolt. It is backed up by two grub screws, which also serve to adjust the position of the cutting edge up to centre. The cutting edge is vertically over the work, and this position allows a liberal stream of cutting compound to be directed on it. It will be seen that there is no strain on the capstan locking bolt, as the revolving steady peg ties up the holder to the work, and the stresses are therefore self-contained.

The form tool has 12 degrees top rake and 3 degrees clearance, while, in addition, the axis of the slot is inclined at 6 degrees to the normal in order to give it side clearance. This side clearance is essential as the blank must necessarily be slightly over size, and the edge of the tool, which first comes in contact with it, acts exactly like a turning tool. The amount of high speed steel used in the form tool is very small in comparison to the length of life, and it can be used up till only a short piece remains. Grinding is also a simple matter, and the tool can be replaced in the correct position without difficulty.

This tool holder is, we understand, giving excellent results, and it is interesting to note that no difficulty is experienced in forming with the automatic feed such a wide cut as the curve on the steel head of the 6 in. Mark IV. shell, which is 37-16 in. wide on the formed part.

### OUR 1916 FIRE RECORD

IN war time, and while many interests are urging thrift and economy, the Canadian people are burning up their created resources at a much greater rate this year than last, is the statement which appears in a bulletin issued by the Conservation Commission on July 7.

During the first five months of 1916 the fire loss in Canada has exceeded that of January to May, 1915, by approximately \$3,000,000, or \$600,000 per month, according to the bulletin. At this rate of increase our fire loss will exceed that of 1915 by \$7,200,000.

Canada has need of all her financial resources. She is borrowing money to

carry on the war, and is paying 5 per cent. interest thereon. The additional fire loss of 1916 would, therefore, pay the interest charge on the recent war loan of \$100,000,000 and would pay \$2,200,000 of the principal. Canada's average annual fire loss, of over \$23,000,000 would pay 5 per cent. interest on approximately half a billion dollars. Our fire loss is, however, something for which we are receiving no value, either financially or patriotic; it is simply a tax, due in great part to carelessness, which Canadians appear willing to pay, and which they, as a whole, are doing little to avert.

### MARKET FOR MANUFACTURED GOODS IN RUSSIA

CONSIDERING the great population in Russia, somewhere in the neighborhood of 170,000,000, and the tremendous area of the country, about one-seventh of the earth's surface, it is not to be wondered at that an examination of the imports of the country shows a wonderful market for manufactured goods of every description, says Kelly's Monthly Trade Review. Manufacturers will find in the following list goods for which there is a good Russian market: Agricultural machinery, building materials, carriages, cast iron, chemicals, coal, coke, cotton, textiles, cotton yarn, electric dynamos and electric motors of all kinds, fertilizers, iron and steel, machinery, knitted and braided goods, leather goods, manufactured copper, motor-cars and cycles, musical instruments, paints and dyes, paper and stationery, machinery parts and apparatus, physical appliances, pig-iron, silk manufactures, tallow and animal oils, tanning materials, timber, woollen manufactures, shoes and boots, hats, ties, scarfs, haberdashery, etc. The match-making industry will probably develop considerably in Russia and there should be a market immediately after the war for match-making machinery.

There is a tremendous demand for beeswax in Russia. In spite of the fact that the total home production averages some 245,000 pounds (equal to 8,847,638 pounds), valued at some £600,500 per annum, imports of beeswax amount to some 8,000,000 pounds annually, more than half of which was hitherto imported from Germany. Owing to the number of churches there is a great demand for candles, which has increased during the war, and it is estimated that there will be a shortage of some 7,500,000 pounds in the coming year. There is a movement on foot to develop the home production of beeswax, and it is proposed to include the study of apiculture in the schools.

### CHASING 60 PDR. SHRAPNEL HEADS ON A NO. 4 CAPSTAN LATHE

THE steel stampings from which the heads of the 60 pdr. shrapnel shell are made are bored and threaded at one end to receive the fuse socket, which is soldered in position. This thread is very short, and, if tapped, the operation must be carried out carefully, otherwise there is a danger of the tap acting as a boring tool and stripping the thread. In addition, taps of this size are both costly and difficult to manufacture to the required degree of accuracy.

An excellent way of threading this work is shown in the line drawing, from which it will be seen that the threads are chased with Herbert standard type circular internal chasers held in the square turret, which also carries a fac-

CHASING 60-PDR. SHRAPNEL HEADS.

ing tool and former for the profiling slide. The threaded portion of the chaser is very much longer than standard, as it has a chamfer or lead  $\frac{7}{8}$  in. wide, which distributes the cut over a number of teeth.

When the thread diameter has been bored, the lathe spindle is reversed and the chaser moved into the position shown by the dotted lines, being set to the correct diameter by means of the cross slide micrometer dial. On engaging the nut with the leader, the chaser travels away from the chuck to the position shown by the full lines, completing the threading at one cut. The advantages of threading by this method are:

- (1)—The chaser is cheaper to manufacture than a tap, as its diameter need not be accurate; it also employs much less steel than a tap.
- (2)—The life of a chaser is much longer than that of a tap.
- (3)—The chasing, being done at one cut, is a quicker operation than tapping, which necessitates reversing the spindle to get the tap out of the work.
- (4)—The diameter of the hole is under the control of the operator, and the wear of the chaser can be allowed for by adjusting the micrometer dial. A tap which has worn below size at once becomes useless.
- (5)—The chaser, having clearance, cuts a much cleaner thread than a tap.

(6)—The holder for the chaser is much less costly than a self-releasing tap-holder.—Herbert's Monthly.

### RUSSIA WILL NEED MUCH MACHINERY

THE Special Foreign Trade Bulletin issued by the Foreign Trade Department of the National Association of Manufacturers of the U.S. is devoted to Russia's requirements. The pamphlet outlines plans for great development of railways, waterways, and other national utilities, calling for immense supplies of machinery and equipment. The publication is intended to keep members advised of developments affecting the export and import trade arising out of the European war as they affect Russia and American manufacturers and exporters desiring to avail themselves of opportunities for extending trade.

"Those who know Russia well," says the Bulletin, "and whose judgment is not affected by the prospect of personal material advantage, are of the opinion that a conservative estimate of the high grade and costly machinery for the completion of public improvements puts the value at over \$200,000,000 for the first year for Government needs alone, and \$100,000,000 for private needs. Furthermore, something like the same ratio of needs and disbursements will continue for at least ten years longer, although in gradually decreasing sums of actual money outlay."

### PROHIBIT ALL TRADE WITH ENEMY COUNTRIES

THE Dominion Government is promulgating through its official publication the full text of the resolutions adopted at the economic conference of the allies in Paris last month, when measures temporary and permanent were instituted to safeguard their mutual economic interests.

They provide for absolute prohibition of all trade with enemy countries. The cancellation of any contracts entered into, the sequestration or control in allied countries of enemy enterprises, further restriction of supplies to the enemy by unifying lists of contraband, etc., making exports to neutral countries conditional on the existence of control organizations or special guarantees, and during and after the war a policy of mutual collaboration and assistance in trade development to offset and counteract the similar policy in contemplation by the Central powers.

The Thor Ironworks, Toronto, have been awarded a contract for the construction of a steel boat 261 feet long for the Great Lakes Transportation Co.

# Foundrymen's Convention and Exhibition at Cleveland, Ohio

Contributed

*It will be noted from what follows that not only are the executive plans well developed for the 1916 Foundrymen's Convention and Exhibition, but the mass of detail arrangement necessary to making the double function a huge success from either or all of the educative, business and social viewpoints, may be said to be more or less finally worked out and completed*

THE exhibition of foundry equipment and accessories, machine tools, etc., to be held at Cleveland, Ohio, during the week of September 11, concurrent with the annual meetings of the American Foundrymen's Association and the American Institute of Metals, will, it is expected, surpass in magnitude any similar undertaking. This is indicated by the large number of manufacturers who already have made reservations for space. Fully 90% of the exhibition area of the Coliseum has been disposed of, and since 10,000 additional square feet will be required to meet the needs of prospective exhibitors, it has been decided to erect a temporary building on a lot directly across the street from the Exhibition Hall. At a meeting of the exhibition committee of the American Foundrymen's Association, held at the Hotel Statler, Cleveland, on Saturday, June 24, the erection of this annex was authorized.

The two buildings will be connected by a runway, making it necessary for the visitors to descend to the street when passing from one to the other. In the temporary structure it is planned to place all of the large operating machines requiring heavy foundations, and it is probable that several different types of melting furnaces will be shown in operation. The annex will be converted into a temporary foundry, where molds will be made and poured. Since the Coliseum was erected, many shows have been held there. The structure affords 60,000 square feet of floor space, but this industrial exhibition will be the first to overflow its generous dimensions, making necessary the erection of a temporary annex to provide space for all of the manufacturers who contemplate making exhibits. This industrial exhibit will, it is believed, be the biggest and most complete show of its kind ever held in Cleveland, and the local interest now manifested points to an unusually large representation of Cleveland products.

## Reservations Made

Although more than two months still intervene before the opening of the exhibition, 95 manufacturers already have made reservations, and the indications are that this total will be swelled to 150 when the doors of the Coliseum and the annex are thrown open on Monday, Sept. 11. At Atlantic City last year there were 102 exhibitors, and never before in the history of the exhibition movement has as much space been reserved

so far in advance of the opening of the show as this year. The complete list of manufacturers who have made application for space follows:

American Gum Products Co., New York.  
Arcade Mfg. Co., Freeport, Ill.  
Armstrong Cork Co., Pittsburgh.  
Atkins, E. C., & Co., Indianapolis.  
Ayer & Lord Tie Co., Chicago.  
B. & B. Mfg. Co., Indianapolis.  
Berkshire Mfg. Co., Cleveland.  
Besly, Chas. H., & Co., Chicago.  
Birkenstein, S., & Sons, Chicago.  
Blystone Mfg. Co., Cambridge Springs, Pa.  
Brass World Publishing Co., New York.  
Brown Specialty Machinery Co., Chicago.  
Carborundum Co., Niagara Falls, N.Y.  
Cataract Refining & Mfg. Co., Buffalo.  
Chicago Pneumatic Tool Co., Chicago.  
Cleveland Blow Pipe & Mfg. Co., Cleveland.  
Cleveland Pneumatic Tool Co., Cleveland.  
Coale, Thomas E., Lumber Co., Philadelphia.  
Curtis Pneumatic Machinery Co., St. Louis.  
Davis-Bourneville Co., Jersey City, N.J.  
Dixon, Joseph, Crucible Co., Jersey City, N.J.  
Excelsior Tool & Machine Co., East St. Louis, Ill.  
Federal Foundry Supply Co., Cleveland.  
Felt & Tarrant Mfg. Co., Chicago.  
Gardner Machine Co., Beloit, Wis.  
General Electric Co., Schenectady, N.Y.  
Gibb Instrument Co., Pittsburgh, Pa.  
Gisholt Machine Co., Madison, Wis.  
Goldschmidt Thermit Co., New York.  
Graceton Coke Co., Graceton, Pa.  
Great Western Mfg. Co., Leavenworth, Kans.  
Hardy, F. A., & Co., Chicago.  
Harriss, Benjamin, & Co., Chicago.  
Herman Pneumatic Machine Co., Pittsburgh.  
Herold Bros. Co., Cleveland.  
Hill-Brunner Foundry Supply Co., Cincinnati.  
Hoewel Mfg. Corporation, New York.  
Ingersoll-Rand Co., New York.  
Iron Age, New York.  
Jennison-Wright Co., Toledo.  
King, Julius, Optical Co., New York.

Lehigh Coke Co., South Bethlehem, Pa.  
Lincoln Electric Co., Cleveland.  
Lupton's, David, Sons Co., Philadelphia.  
McCormick, J. S., Co., Pittsburgh.  
MacLean Publishing Co., Toronto, Ont.  
Macleod Co., Cincinnati.  
Mahr Mfg. Co., Minneapolis.  
Malleable Iron Fittings Co., Branford, Conn.  
Manitowoc Electric Implement Co., Manitowoc, Wis.  
Metal Industry, New York.  
Midland Machine Co., Detroit.  
Moldar Co. (Richey, Brown & Donald), Maspeth, N.Y.  
Moltrup Steel Products Co., Beaver Falls, Pa.  
Monarch Engineering & Mfg. Co., Baltimore.  
Moteh & Merryweather Machinery Co., Cleveland.  
Mott Sand Blast Mfg. Co., Chicago.  
Mumford, E. H., Co., Elizabeth, N.J.  
National Engineering Co., Chicago.  
New Haven Sand Blast Co., New Haven, Conn.  
Norma Co. of America, New York.  
Norton Co., Worcester, Mass.  
Obermayer, S., Co., Chicago.  
Oliver Machinery Co., Grand Rapids, Mich.  
Osborn Mfg. Co., Cleveland.  
Oxweld Acetylene Co., Chicago.  
Pangborn Corporation, Hagerstown, Md.  
Penton Publishing Co., Cleveland.  
Pickands, Brown & Co., Chicago.  
Portage Silica Co., Youngstown, O.  
Pridmore, Henry E., Chicago.  
Pyrotecrite Co., Chicago.  
Robeson Process Co., New York.  
Rogers, Brown & Co., Cincinnati.  
Sand Mixing Machine Co., New York.  
Slv. W. W., Mfg. Co., Cleveland.  
Smith Facing & Supply Co., Cleveland.  
Smith, R. P., & Sons Co., Chicago.  
Smith, Werner G., Co., Cleveland.  
Snyder Electric Furnace Co., Chicago.  
Standard Sand & Machine Co., Cleveland.  
Sterling Wheelbarrow Co., West Allis, Wis.  
Stevens, Frederic B., Detroit.  
Strong, Kennard & Nutt Co., Cleveland.  
Sullivan Machinery Co., Chicago.  
Superior Band Co., Chicago.  
Thomas Elevator Co., Chicago.

Titanium Alloy Mfg. Co., Niagara Falls, N.Y.

Union Steam Pump Co., Battle Creek, Mich.

U. S. Graphite Co., Saginaw, Mich.

U. S. Molding Machine Co., Cleveland.

Wallace, J. D., Chicago.

Warner & Swasey Co., Cleveland.

White & Bro., Philadelphia.

Whiting Foundry Equipment Co., Harvey, Ill.

Woodison, E. J., Co., Detroit.

### Papers and Reports

The papers and committee reports to be presented at the annual meeting of the American Foundrymen's Association promise an unusually valuable and interesting programme. Separate sessions will be held for the discussion of topics relating to the manufacture of gray and malleable iron and steel castings. The opening meeting will be held at the Hotel Statler, Monday afternoon, September 11, and will be followed by morning sessions only, the convention closing Friday, September 15. This arrangement will afford the foundrymen more opportunity to inspect the exhibition than has been the case in former years with two sessions daily, although the length of the programme will necessitate several simultaneous meetings. Three symposiums will feature the programme, the subjects of which follow:

"Results of Closer Co-operation between the Engineer and the Foundry as relating to Gray and Malleable Iron, Steel and Non-ferrous Metals."

"The Influence of Gating on Castings, including Gray and Malleable Iron, Steel and Non-ferrous Metals."

"Electric Furnace Practice as Relating to the Production of Steel Castings."

Four authors will present papers for each of the symposiums, and every phase of these respective subjects will be discussed. Several interesting papers on sand reclamation also will be presented, covering investigations made among all of the members of the American Foundrymen's Association and by the United States Bureau of Standards. A partial list of papers promised follows:

### Miscellaneous

"Sand Reclamation," by H. B. Swan, Cadillac Motor Car Co., Detroit.

"Progress Report on Sand Reclamation," by C. P. Karr, associate physicist, U.S. Bureau of Standards, Washington.

Symposium on "The Results of Closer Co-operation between the Engineer and the Foundry," as relating to

"Gray Iron," by D. W. Sowers, Sowers Mfg. Co., Buffalo.

"Steel," by John Howe Hall, Taylor-Wharton Iron & Steel Co., High Bridge, N.J.

"Malleable Iron" (author not yet determined).

"Non-Ferrous Metals," by C. E. Chase, Modjeski & Angier, Chicago.

Symposium on "The Influence of Gating on Castings," including

"Gray Iron," by B. D. Fuller, Westinghouse Electric & Mfg. Co., Cleveland.

"Steel," by William Gilmore, Hubbard Steel Foundry Co., East Chicago, Ill.

"Malleable Iron," by A. M. Fulton, Fort Pitt Malleable Iron Co., Pittsburgh.

"Non-Ferrous Metals," by R. R. Clarke, Pennsylvania Railroad Co., Pittsburgh.

"The Significance of the Fire Waste," by Franklin H. Wentworth, secretary National Fire Protective Association, Boston.

"Profit Sharing in the Jobbing Foundry," by C. E. Knoepfel, New York.

"What the Pratt Institute Has Done, Is Doing, and Hopes to Do, in the Training of Men for the Foundry Industry," by Samuel S. Edmands, Pratt Institute, Brooklyn.

"The Installation of Uniform Cost Systems by Members of Technical Societies," by Clinton H. Scovell, Clinton H. Scovell & Co., Boston.

"Report of the Committee on Foundry Costs," by B. D. Fuller, chairman, Westinghouse Electric & Mfg. Co., Cleveland.

"Report of the Committee Advisory to the U. S. Bureau of Standards," by Richard Moldenke, chairman, Watchung, N.J.

"Report of the Committee on Safety and Sanitation," by Victor T. Noonan, chairman, Industrial Commission of Ohio, Columbus.

"Report of Representatives on the Conference Board on Training of Apprentices," by B. D. Fuller, chairman, Westinghouse Electric & Mfg. Co., Cleveland.

### Gray Iron

"The Effect of Different Mixtures on the Strength of Chilled Car Wheels," by G. S. Evans, Lenoir Car Works, Lenoir City, Tenn.

"The Manufacture of Semi-Steel Castings," by David McLain, McLain's System, Milwaukee.

"The Use of By-Product Coke in Foundry Operations," by George Long, Pickands-Brown & Co., Chicago.

"How Certain Cleaning Room Problems Have Been Solved," by H. Cole Estep, The Foundry, Cleveland.

"The Use of Borings in Cupola Operations," by James A. Murphy, Hooven, Owens & Rentschler Co., Hamiltion, O.

"One-third of a Century in a Gray Iron Foundry," by A. O. Backert, Penton Publishing Co., Cleveland.

"The Experimental Foundry," by H. K. Hathaway, Tabor Mfg. Co., Philadelphia.

"Report of Committee on Standard Methods for Coke Analysis," by H. E. Diller, chairman, General Electric Co., Erie, Pa.

"Report of Committee on Standard Specifications for Foundry Scrap," by G. E. Jones, chairman, Whiting Foundry Equipment Co., Harvey, Ill.

"Report of Committee on General Specifications for Gray Iron Castings," by W. P. Putnam, chairman, Detroit Testing Laboratories, Detroit.

### Steel

Symposium on "Electric Furnace Practice for the Manufacture of Steel Castings," by F. T. Snyder, Snyder Electric Furnace Co., Chicago; A. B. Clarke, Buchanan Electric Steel Co., Buchanan, Mich.; John A. Crowley, John A. Crowley Co., New York.

"Making Electric Steel in the Rennerfelt Flaming Arc Furnace for Foundry Purposes," by C. H. Vom Baur, Hamilton & Hansell, New York.

"Crucible and Electric Steel Compared," by T. S. Quinn, Lebanon Steel Foundry, Lebanon, Pa.

"Converter and Electric Steel for Casting Purposes Compared," by Peter Blackwood, Monarch Steel Casting Co., Detroit.

"Manganese Steel Castings," by W. S. McKee, American Manganese Steel Co., Chicago, Ill.

"Titanium in Steel Castings," by W. A. Janssen, Bettendorf Co., Davenport, Iowa.

"Report of Committee on Steel Foundry Standards," by Dudley Shoemaker, chairman, Atlantic Steel Casting Co., Chester, Pa.

"Report of Committee on Specifications for Steel Castings," by John Howe Hall, chairman, Taylor-Wharton Iron & Steel Co., High Bridge, N.J.

"The Small Open-Hearth as a Flexible Unit for Either Large Steel Foundries or General Jobbing Shops," by Frank Carter, Milwaukee.

"The Presence of Alumina in Steel," by G. F. Comstock, Titanium Alloy Mfg. Co., Niagara Falls, N.Y.

"The Particular Application of Green Sand Molding in the Steel Foundry," by A. F. S. Blackwood, Monarch Steel Casting Co., Detroit.

"Theory and Practice of Heading and Gating Steel Castings," by Ralph H. West, West Steel Casting Co., Cleveland.

"Acid versus Basic Steel for Making Castings," by E. F. Cone, The Iron Age, New York.

"Alloy Steel Castings," by David Evans, Chicago Steel Foundry Co., Chicago.

### Malleable Iron

"The Application of Malleable Iron Castings in Car Construction," by Frank J. Lanahan, Fort Pitt Malleable Iron Co., Pittsburgh.

"Commercial Side of the Malleable Iron Industry," by W. G. Kranz, National Malleable Castings Co., Cleveland.

"Report of Committee on Specifications for Malleable Iron Castings," by

Enrique Touceda, chairman, Albany, N.Y.

Papers will be presented on various subjects relating to malleable iron practice, by the following authors:

Edwin F. Leigh, Marion Malleable Iron Works, Marion, Ind.

S. H. Standish, North-Western Malleable Iron Co., Milwaukee.

G. Meehan, Ross-Meehan Foundry Co., Chattanooga, Tenn.

Enrique Touceda, Albany, N.Y.

W. A. Forbes, Rockford Malleable Iron Works, Rockford, Ill.

#### Entertainment and Plant Visitation

To provide for the entertainment of the visiting foundrymen and to direct them in plant visitation, local committees have been organized, the chairmen of which held their first meeting at the Hotel Statler, Cleveland, on Saturday, June 24.

F. B. Whitlock, Interstate Foundry Co., has been appointed chairman of the general directing committee, which consists of the chairmen of the other committees, as follows:

Plant Visitation—J. S. Smith, Smith Facing and Supply Co.

Entertainment—Sterling Hubbard, Rogers, Brown & Co.

Reception—Herbert Boggis, Taylor & Boggis Foundry Co.

Golf—W. B. Greene, Palmer & De Mooy Foundry Co.

Finance—J. C. Brainerd, Johnston & Jennings Co.

Ladies' Entertainment—Mrs. W. C. Sly, 13474 Lake Avenue.

An unusually complete entertainment programme is being developed, which includes the annual banquet of the American Foundrymen's Association and the American Institute of Metals, at the Hotel Statler, Thursday evening, Sept. 14. Every opportunity also will be afforded for plant visitation. Cleveland is one of the leading foundry centres of the United States, and practically all of the castings manufacturers will permit the inspection of their plants during convention week.

In view of the great activity prevailing in the foundry industry, making necessary the almost continuous service of every available employee, many foundry operators are planning the vacations of their plant executives for convention week. That the attendance will eclipse all previous records is indicated by the interest already manifested, and large delegations of foundrymen will travel in a body from Detroit, Pittsburgh, Chicago, Milwaukee, Buffalo and Philadelphia.

#### BLAST PREHEATING CUPOLA

A NEW type of cupola, in which the blast is preheated before coming in contact with the fuel, is described by J. A. Parsons in a recent issue of the Journal

of the South African Institute of Engineers. The air passes through a series of tubes in the chimney of the cupola, after which it is blown through the tuyeres to the fuel. When the blast is first started, the air reaches the fuel bed only slightly warm. Within a few minutes it reaches the temperature of melting lead, and at the end of about 20 minutes it attains a temperature about one-third of that to be imparted to the iron.

Economy in the use of coke is obtained by means of the preheater, due to the fact that only about one-half of the coke is burned to CO<sub>2</sub> in the neighborhood of the tuyeres, the other half being burned to CO which later burns to CO<sub>2</sub> in the chimney. The burning of the coke to CO generates 4320 B.t.u., and

ARRANGEMENT OF BLAST PREHEATING CUPOLA.

the burning of CO to CO<sub>2</sub> generates an additional 10,220 B.t.u. Inasmuch as this additional heat is generated after the CO has passed the iron in the cupola, its heating effect is lost. The preheater located in the chimney recovers a large portion of this heat and returns it to the cupola in the blast. The economy in coke claimed for the preheater, as the result of several months' operation, is 30 to 39 per cent., according to the duration of the cast.

It is also claimed that the quality of the metal is improved, and that the tuyeres do not clog up. The furnace can be temporarily held up, by diminishing the blast, yet the remainder of the blast comes in so hot that the melting can be reduced in proportion and without cooling the furnace unduly. This latter feature permits of great flexibility of operation. Furthermore, the capacity of the cupola is much increased. A 24-in. cupola can handle up to 2 tons of iron per hour with a 6-oz. blast. After some seven months' operation no deterioration of the preheater is noticeable. This results in a low first cost and small repair charges.

#### TRAINING MUNITION OPERATORS IN BRITAIN

IN order to train workers for employment in the numerous factories throughout Great Britain, the Ministry of Munitions some months ago decided to establish a number of training schools. It was not anticipated, at the outset, that anything further would be achieved than that certain numbers of unskilled workers could be taught to perform correctly one single operation. As a fact, a good deal more than this has been done in some cases, but, broadly speaking, what is actually being effected is that each student is taught how to do one thing and to do it well enough to ensure that the work produced is satisfactory and to gauge.

##### Instruction Schedule

These training centres are intended, if not to supplant, at any rate to supplement the teaching which is being carried out at the factories themselves, and it can be said of them that they have been exceedingly successful. For the carrying out of its idea the Ministry of Munitions quickly turned its attention to the various technical schools owned by local authorities throughout the country, and from them it, apparently, met with a ready response. At the present time there are over sixty training centres under the control of the Ministry in which instruction is being given to persons desirous of entering munition works.

The training is free in all the sixty-four centres, and in the Metropolitan area they are under the control of the London County Council. Each student must undertake to enter a munition factory at the close of the course of training. In London the normal course is six weeks, the students working for four hours a day for six days a week. The total duration of the training is, therefore, 144 hours. The day is divided into three periods of four hours each, these being from 9 a.m. to 1 p.m., from 2 p.m. to 6 p.m., and from 6.30 p.m. to 10.20 p.m. respectively. Hence the school is open for 72 hours per week, and three sets of students can be in training at one time. The teaching staff is so arranged that each individual is on duty for half of the day—that is to say, each works 36 hours per week. Two definite classes of students are trained—(a) ordinary operators at the vise and machine tools and (b) tool setters on lathes, milling and allied machines. In July of last year, when the control was taken over by the Ministry of Munitions, the particular work shop under review contained the following equipment:—Thirty lathes, 11 drilling machines, 3 power hack saws, 2 shaping machines, 1 punching machine, 1 shearing machine, and 45 vises. Since that time the following machines have been added:—Six capstan lathes, 12 milling machines, including

profiling machines, 3 lathes for 18-pdr. cartridge cases, 2 turret lathes for 18-pdr. shells, 2 tool grinders, 2 universal cutter grinders, 1 slotting machine. Further machines are about to be installed. The motive power is obtained from four electric motors, which drive on to three main lines of shafting, each about 100 ft. long.

#### Organization

The organization of the school has been arranged to follow as nearly as possible that of a munition factory, there being offices, stores, refreshment rooms, machine, fitting and blacksmiths' shops. Ordinarily speaking, set schemes are worked to, but in special cases where requisition is made by individual firms for workpeople trained to meet particular needs, special training—sometimes with tools actually lent by the firms in question—is given.

Students are trained in a large number of operations, such as the use of files; operating capstan and turret lathes; or taking charge of milling, drilling, slotting and grinding machines. In some cases the work produced—such as base-plates for shells, is for actual use. Other students again learn how to forge, form and sharpen tools, etc. Naturally, as is to be expected, the character of the work being turned out varies, for there are students in different stages of training. There are to be seen, for example, tools and gauges of various forms which would do credit to any workshop. The training is eminently practical and calculated to produce the desired result, namely, the making of each student as proficient as possible in one particular operation in the shortest time. Women students are of all ages. Some are quite young, while others have reached middle life. They all appear to enter wholeheartedly into the work.

In London there are five centres conducted by the London County Council. Two of these are exclusively devoted to the teaching of gauge making, the working hours being 44 per week. Up to the present time over 3,000 students have received certificates, and of these over 2,700 are known to have entered munition factories or his Majesty's forces. Students have been supplied to 338 individual firms, one of which has taken no less than 344, while 18 have taken more than twenty each.

#### PRODUCING THIN METAL PANS

ACCORDING to the International Moulder's Journal, the extremely thin metal pans made by the Chinese for cooking rice with a minimum amount of fuel are cast in moulds—which are made in two parts—of well-kneaded clay by means of a potter's wheel. When dried the moulds are again placed on the wheel and coated with a very thin layer of moulder's sand, and, after being re-

dried, the two halves are fitted together with the greatest care, since even the slightest relative displacement would spoil the casting. The next step is to bake the moulds, until they are as hard as brick, at red heat in a furnace filled with charcoal and topped by a banded fire-clay cover.

Meanwhile the iron for pouring is melted in a small crucible-like cupola furnace, so that the metal will have attained the requisite fluidity by the time the mould is at a bright red heat, whereupon the cover of the baking furnace is taken off, the metal poured into the mould, and the cover replaced for the casting and mould to cool down together, which takes about two days. The mould is then carefully taken apart, the pan detached, and the casting gate removed with a fine saw. The pan is fitted with wire handles, inserted through drilled holes, and is ready for sale. The moulds can be used for several pourings, being recoated with fine sand every time.

#### WOMEN MAKING GOOD ON MUNITIONS

THE other day I met a friend who is a highly placed official at one of the largest works in Sheffield, England, says an engineer correspondent. We discussed the labor outlook. The great difficulty, he said, is in getting a full supply of really skilled men—men who are fitters as well as turners. For ordinary shell turning any man of intelligence, and with the slightest taste for that kind of thing, can be sufficiently trained in a day or so to commence work—the rest comes with experience. I asked how the experiment of women munition workers was progressing, and was assured that it had quite passed the experimental stage. "We do not know," he added, "what we should do without them now. They are proving far better than our highest anticipation."

#### Women Save the Situation

In fact, women in the munition factories are going to save the situation. They are in real earnest, and show great adaptability. They are willing to be taught, and quickly learn." I have received similar testimony in other directions, and it is rare for one of them to come before the tribunals for any offence. Many of the women have temporarily abandoned good social positions. Clad in khaki overalls, and a very becoming head-dress, they sink all such distinctions and work for the common good.

One very remarkable case in their favor has been related to me. It occurred in this district. A new shell shop was fitted up with lathes for turning 18-pounder shells—a nice light job for youths. The shop was filled with lads who had received preliminary instruction in their duties. After a certain

period of grace, during which they were expected to pick up sufficient experience, it was estimated that the output should have been, say X thousand shells weekly. What was the actual fact? The output never rose above a tenth of that amount, and within six months there was not a lathe in the place that had not been broken in some way or other.

#### Employment Provision Amplified

These youths were all cleared out, the pick being transferred to other shops, and the remainder dismissed. The place was reorganized and filled with women. Within six weeks they were working so well that the weekly output had risen to 500 beyond the original estimate—and all the machines were intact. Of course, the great difficulty of a more rapid extension of the employment of women is that the works were built for male labor, so that the sanitary and other arrangements of the places have had to be reorganized. In some cases this has been done upon a very elaborate scale, and one or two large works, I believe, are on the eve of huge extensions of female labor.

It is now being recognized that women can do almost anything. Men employed as laborers for the rough work of sweeping and cleaning, if they become awkward or unsatisfactory, as they have a knack of doing at times, are being quietly dropped in favor of women suitable for such work, and of a class well able to take care of themselves in rough surroundings. They work side by side with men, in some cases, but always under their own forewoman, and are answering the purpose well. It is quite anticipated that women will shortly be employed in the turning, etc., of a very much heavier type of shell. Already in some factories they are engaged in such work as operating steam cranes, working in khaki trousers and overalls, and at one factory—I have no need to be more definite—there are already 4,000 women hard at work on munitions, whilst preparations are well advanced to receive as many more. These are great times for patriotic women, and they earn good wages, too.

It is reported by H. M. trade commissioner for Australia that the New South Wales Minister of Agriculture has recently entered into an agreement with a firm of engineers for the supply of plans and specifications for elevators for the bulk handling of grain in the State. It is anticipated that the first building to be erected, namely, the Sydney Terminal Elevator, will be undertaken during next month. New South Wales will, it is stated, be the first State in the Commonwealth to handle grain in bulk by elevators.

# PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

## SELF-CONTAINED GRINDING MACHINES

**T**WO additional sizes—8 in. x 18 in. and 8 in. x 30 in.—have been added to the line of self-contained grinding machines built by the Modern Tool Co., Erie, Pa.

Economy of floor space, compactness, ease of operation, and comparative simplicity of mechanism are distinguishing features of these machines, all operating levers being concentrated on the front of the machine, and no parts extending above the wheel stand. These machines are essentially manufacturing grinders for straight or taper cylindrical work in quantities, the accessibility allowing parts to be properly cared for without undue expenditure of time.

The bed is a one-piece casting, rigidly

any of the recognized standard grinding wheels. Wheels used on the standard machines are 16 in. diameter up to 3 in. face. Wheels used on the heavy drive are 18 in. up to 4 in. face.

The table drive is of a very simplified type, eliminating what was formerly known as the table transmission. This table drive consists of a single unit contained in the bed of the machine which is a combination of table drive and transmission. All steel spur gears are used for the reversing mechanism. The power table traverse is controlled by a lever immediately left of the table hand wheel, which provides for starting or stopping the table at any point in its stroke. When the table is under power the hand wheel is automatically disengaged and when the power is re-

instantly changed to any feed while the machine is still in operation.

The headstock is of entirely new design being driven from a shaft under the sliding table. This shaft is driven by a pulley which is carried in a bracket on the bed, on which power is taken from the gear box.

A feature of the headstock is the combination of live and dead centres. The spindle is carried in bearings in the headstock base in which it revolves for live centre work. The face plate is clamped to the spindle and the spindle revolves in the headstock bearing for live centre work. To change for dead centre work it is only necessary to loosen a screw which clamps the face plate to the spindle and tightens the clamp on the headstock which holds the

FRONT VIEW 8 IN. X 18 IN. MACHINE.

REAR VIEW 8 IN. X 18 IN. MACHINE.

braced to insure stability, while the base rests upon three points.

The standard wheel spindle is  $2\frac{1}{4}$  in. diameter running in phosphor bronze bearings  $6\frac{1}{4}$  in. long, driven by a belt 4 in. wide. For exceptionally heavy duty work, however, they can be furnished with a wheel spindle  $3\frac{1}{4}$  in. in diameter running in phosphor bronze bearings  $8\frac{1}{4}$  in. long driven by a belt 5 in. wide, with a corresponding increase in the wheel stand pile, the bearings in each instance being provided with sight-feed oilers.

The wheel stand pile is bolted to the bed of the machine. The wheel stand slides on V and flat ways, and is held in place by gravity, but is provided with a safety gib to guard against lifting under abnormal conditions. The wheel centre is of large diameter, has a long bearing on the spindle, and will take

moved the hand wheel is automatically engaged for traversing the table by hand. There are four table feeds, derived from a single unit gear box, and controlled by a lever at right immediately below the table hand wheel.

The automatic cross feed is positive in its action and can be set for a reduction of any amount from .0005 in. to .005 in. at either or both ends of the table reverse. This latter feature is especially advantageous when grinding against a shoulder. The feed is automatically thrown out when work is ground to size and a positive stop is provided for use when feeding by hand.

The cross feed hand wheel is graduated to .0005 in. in plain view of the operator. Adjustment of the cross feed is made by the movement of a lever to the amount of feed desired, as indicated on a graduated dial plate, and may be

spindle firmly in the headstock base. The dead centre pulley is then free to revolve upon its bearing for regular dead centre work.

The foot stock is fitted to the swivel table and preserves its alignment in the same manner as the headstock. The foot stock spindle is held in any position by a spring, or may be set positive against the work and locked. The work centres on the head and foot stock, are directly over and between the guides of the table, a construction which eliminates the weight and strain necessarily present where the work centres are outside.

These two machines have eight work speeds from 26 to 390 r.p.m., and four table feeds from 22 in. to 104 in. per minute. The feeds and speeds are entirely independent of each other, and are suitable for the various classes of

work which come within the range of these machines.

All work speeds and table feeds are controlled by levers on the front of the machines and are derived from a sep-

swinging stop, and a limited adjustment is provided for, by a set screw and lock nut in the stop, so that the enlarged end of the spindle actually bears against end of shell, to locate the band the proper

at the rear of the particular bearing.

The tool base is bolted firmly to the bed and carries both roughing and finishing heads. On the 9.2 in. the roughing is split into two operations. Each tool is fully adjustable but when once set they can be removed and replaced with precision. The feed of both tools is by a single screw to positive stops. The undercutting tool is on a separate block mounted on the front slide at the correct angle and is fully adjustable. The feed is through lever and cam. The rear or finishing tool is so mounted that the tool slides past the band and shears it to exact size and shape. The feed is by rack and pinion with handle in a convenient position for the operator.

#### BENCH MILLER WITH ADJUSTABLE HEAD

THE illustration and description refer to a bench miller of the adjustable head type. It can also be furnished mounted on a column. The head slides up and down the column by means of a rack and segment operated by a lever, which can be placed in two positions to suit the convenience of the operator, and is arranged with micrometer depth gauge. It is counterbalanced by a weight which is adjustable to take care of different size cutters or arbors. In this way the head can be quite accurately balanced.

The spindle runs in bronze bearings, the front bearing being taper and adjustable for wear. The back shaft also runs in bronze bearings. Six speeds are obtained through the three-step cone, and by reversing the pulleys on the end of spindle and end of back shaft. The table traverse is operated by lever through rack and pinion. The saddle is fed in and out by means of a square thread screw, which has a micrometer

LARGE SHELL BAND TURNING MACHINE

arate unit gear box. The gears are made of specially treated steel and are in mesh at all times.

The main drive is in the rear of the machines and runs at constant speed, power being applied either from a line shaft by a single belt or by motor connection. Wheel truer, steady rests, and pump are supplied with the regular equipment.

#### LARGE SHELL BAND TURNING MACHINE

THE type of single purpose band turning machine originated by the Jenckes Machine Co., Sherbrooke, Que., has been extended to include shells of the larger sizes, and the accompanying photo shows the 9.2 in. size for machining the driving bands on shells of that size.

The bed is deep and wide, of heavy box section with box cross girts. The bearings are cast integral with the bed, the front bearing being 9 3/4 in. dia. by 7 in. long, and the rear 6 in. dia. by 7 in. long. The bearing caps are machine fitted and secured by four heavy studs. The forward cap is interlocked with the bearing to take the end thrust without end shift. Both bearings are lined with heat babbitt peened in, bored and finally scraped to the spindle. Shims are provided, so that wear can be taken up in an effective manner.

Tailstock.—The exact position of the tailstock spindle is determined by a

distance from end of shell. A heavy center working in a hardened bushing centers the shell on the spindle. This center retreats slightly against the pressure of a heavy spring inside the spindle, and permits some variation in depth of center in adapter plug.

The hollow driving spindle is of steel. The chuck is built into the extension of the spindle and is of the collet type, the jaws being opened and closed positively by compressed air. It is operated by an air cylinder at the rear. In closing the jaws, the shell is pushed forward until stopped by the tail spindle. Jaw movement continues until the full pressure of the cylinder is exerted. The drive is through a single clutch pulley, 22 in. diam., 10 1/2 in. face. The pulley is bronze bushed and runs loose on the spindle. The clutch is the full diameter of the inside of the pulley and is of the taper cork insert type.

It is operated by a separate valve, and the release is by springs. The thrust of the spindle is taken at the forward end bearing, a take-up collar being provided

BENCH MILLER WITH ADJUSTABLE HEAD

attachment. The specifications are as follows:—Size of table, 4 in. x 15 in.; table feed, 6 in.; vertical travel of head, 5 in.; taper in spindle, No. 7 B. & S.;

spindle speeds with three-step cone, 120, 180, 270, 480, 720, and 1,080 r.p.m.; counter shaft speed, 360 r.p.m. The Morris Machine Tool Co., Court and Harriet Streets, Cincinnati, Ohio, are the manufacturers of this bench miller.

### TWIN TROLLEY FOR 160-TON A.C. CRANE

ONE of the largest alternating current cranes yet installed for handling locomotives has been furnished recently by Whiting Foundry Equipment Co., Harvey, Ill., to the Seaboard Air Line Rail-

TWIN TROLLEY FOR 160-TON A.C. CRANE

way for their new shops at Portsmouth, Va. The crane is 160 tons capacity, with two 80-ton trolleys, one of which is equipped with a 10-ton auxiliary hoist. The trolleys are of the construction shown in cut, and embody many valuable features.

Among these are the fact that the entire train of gears is enclosed and runs in oil bath. The motor pinion has outboard bearing as shown. The idler sheaves are mounted on separator in place of being hung on, thereby allowing the operator to inspect rope and oil sheaves while standing on top of the trolley, and also increasing lift of crane by about 30 inches. With the exception of drum shaft, no other shafts extend across the trolley.

All shafts in gear train are on the same line, and are of cast steel, machine cut. Pinions are forged, as is the drum gear. Trolley sides and separator are of cast steel, the housing being of structural steel, provided with proper hand holes to allow for inspection and easy removal for making repairs.

### OPENING FOR MACHINERY IN TRINIDAD

EDGAR TRIPP, Canadian Commercial Agent in Trinidad, B.W.I., writes as follows concerning the importation into that island of general machinery:—

Official statistics give no details regarding the different kinds of machinery imported. The whole is lumped together, except a small portion admitted at the preferential rate of duty. The trade is fairly important, and is likely to become more so if the fiscal arrangements for which all the colonies are striving take effect after the war. In that case a great impulse would be given to sugar cultivation, an industry which if assured of the same measure of preference in the United Kingdom as is accorded in Canada, would no doubt develop enormously.

At present, want of confidence in the future, generated by painful experience in the past, prevents any one interested in a sugar factory or plantation doing more than is actually necessary to keep things from year to year. Even so, the importation of sugar machinery is extensive. It is by far the largest item, the importation of which is from the United Kingdom, although water tube boilers from the United States are

found among big concerns. Large renewals and repairs are, of course, of annual necessity, but for the present there is no prospect of new sets of works being erected. Most of the sugar estates are owned or controlled in the United Kingdom, and the local representatives have no say in deciding where orders shall be placed.

For the two years ending December 31, 1915, the total value of machinery imported was about £150,000 each year. Much of this was required for the new oil fields, and in this case the United States came in for a full share, amounting to nearly £100,000 in 1914, and £88,000 in 1915. Almost all this class of machinery was on the free list until December 10, 1915, when a 2½ per cent. duty was imposed, with other imposts necessary during the war. Canada only figured for £42 in 1914, and £26 in 1915, in the latter case not even claiming the preferential of 2 per cent.

Most of the machinery required for agricultural and commercial purposes is imported direct by the owners of the factories or works in which it is to be used and, being not for sale, is among the items formerly free, but now paying 2½ per cent. Motor and other engines, electrical machinery, etc., imported for sale, are subject to a general tariff of 10 per

cent., and a preferential tariff of 8 per cent. Apart from sugar factories, oil refining, and asphalt works, there are a certain number of foundries, rice mills, coconut oil factories, chocolate and match works, and one brewery, but all or nearly all obtained their plant direct, and not through dealers. Large numbers of sewing machines, and a certain quantity of printing press machinery are also imported.

A good active man from Canada, representing various classes of machinery has an opportunity now, such as has not occurred before of securing business, seeing that it is impossible to get orders executed in England or Scotland within anything like a reasonable time, and if the Dominion does not take advantage of this, some other country will.

### MACHINE TOOLS ON BOARD SHIP

THE amount of damage to both fleets engaged in the recent sea battle draws attention incidentally, to the use of power driven tools on warships for effecting a multitude of repairs or alterations. Although it is not permissible to mention how far the British navy is equipped in that respect, one is at liberty to state that the ships of the world fleets as a rule are inadequately supplied with power-driven tools.

No doubt this applies more particularly to the mercantile marine, but facts give it force in relation to the warships of a number of Powers and it may not be an exaggeration to affirm, that the majority of modern steamships are deficient in tools of a character suitable for a long and economical range of work.

In many instances a nondescript lathe constitutes the "plant," and a current paragraph reports that the captain and crew of a broken down steamer had nothing more effective than chisels with which to plane or otherwise treat a new steel mast. One writer considers that a lathe, drilling machine, and high-speed grinder (capable of separate use) should be part of a ship's equipment, and he mentions several incidental items as very useful additions. So much damage has been done to the world's shipping by the war that the value of machine tools on a ship is now beyond question. There ought to be no difficulty in arranging that some of the men on board are capable of using such tools.

**U. S. Steel Unfilled Tonnage.**—The unfilled orders of the United States Steel Corporation on June 30 stood at 9,640,458 tons, a decrease of 297,340 tons compared with those on May 31, according to the monthly statement of July 10.

### STIMULATING OVERSEAS SERVICE RECRUITING

THESE is every indication that good progress is being made with the scheme of introducing more and more female labor into our factories, workshops and offices. An interesting feature is, of course, the entrance of women into spheres of activity to which in Canada at least they have not so far aspired or have been admitted. By this we mean particularly their employment in the production of munitions of a variety type. In Great Britain many thousand women are employed in shell plants, their work being as diversified as the shells themselves and their component parts, and just as many thousands are engaged in other forms of war-created commodity production and necessity, the opportunity afforded being the result of male enlistment and making possible the latter to become still more fully available.

In numerous cities and towns throughout Ontario at least, many women have registered so as to enable eligible men to join one or other of the overseas battalions now completing, or yet to be organized, and the movement is rapidly gathering impetus. It has, as a matter of fact, began already to make itself felt beneficially in the output of our metal-working plants, all of whom have been more or less handicapped of late, due to absorption of male help for overseas service.

The venture is a laudable one, the double purpose served being effective and valuable; besides, what Britain can do, Canada can do equally well. We look to see considerable development take place within the next few weeks in the matter of female employment in our munitions plants, the at least maintenance of output and the increased male enlistments being the desirable outcome.

Supplementary to the movement to increase the numbers and activity scope of women munition workers in our metal-working and kindred plants, and indicative of a proposition that may easily produce highly satisfactory returns, is the action taken a few days ago by the Committee on Recruiting of the Montreal Board of Trade. The aim is to have returned soldiers and men who have been rejected fill the places of those operators in our munitions plants who can measure up to the standard of service fitness. Although munitions plants are meantime more directly involved in the scheme of things, it is expected in the end to include the whole wide range of manufacturing enterprise. The idea is, of course, not Government conscription, but a somewhat severe form of compulsion on the part of employers, in order to ensure that men who

should be at the front are at least not retained on work that can be done by those who have been in the trenches, or who have shown their desire to serve, and have been rejected.

In addition to Huntley Drummond, of the Board of Trade Committee on Recruiting, representatives from the following companies were present at the meeting called to formulate ways and means:—Northern Electric Co.; Montreal Locomotive Works; Darling Bros., Ltd.; Steel Co. of Canada, Ltd.; St. Lawrence Machinery Co.; B. W. Coghlin Co.; Canada Tube & Iron Co.; Dominion Bridge Co.; Canadian Car & Foundry Co.; John McDougall Caledonian Iron Works. After considerable discussion it was suggested by the chairman that Lieut.-Col. Clarence F. Smith, president of the St. Lawrence Machinery Co., form a committee representative of the leading munition manufacturers of Montreal and district, which would go into the whole subject of recruiting and its relation to manufacturing output.

To those familiar with the commercial and industrial activities of the City of Montreal, the detail of representative attendance is impressive and lends color to the idea that action along the lines indicated will not only have strong support, but will receive early exemplification in practice.

### THE LURE OF EXPORT TRADE

AS might be expected, the lure of export trade is not all-embracing in its appeal. This is not to be wondered at, in view of the many considerations and variety circumstances attendant on its successful or even worth-while prosecution. To begin with, many manufacturing concerns—large as well as small, have a domestic clientele which whether in war or peace times monopolizes approximately their production capacity. The net revenue from such sources has been proven not only ample, but without exception, reasonably free from curtailment by losses more or less incidental to all business enterprise. In view of this, they not unnaturally conclude that others less favorably situated or whose product more readily approaches the export requirement, should have all the scope possible.

To participate in export trade calls for abundant financial resources, also equal, if not more close attention to its claims than that deemed necessary for domestic requirement; and, last, but not least, a keen appreciation of the fact that many of the ideas and methods employed in catering to a domestic trade are not only capable of, but require a radical readjustment. In a word, a properly constituted export department is a sine qua non, with every manufacturer who would begin to lay himself out for the successful prosecution of trade beyond the confines of the territory which to him spells "domestic." It is so easy to allow the demands and requirements of the latter to unfavorably influence the former, as to bring about the inevitable result—failure, disgust and regret.

### THE FOUNDRYMEN'S CONVENTION AND EXHIBITION

THE American Foundrymen's Convention and Exhibition at Cleveland, Ohio, is now less than two months away, an interesting reminder of the fact being had from the comprehensive detail covering the double function which appears in another section of this issue. The indications are such that no progressive Canadian foundry enterprise can without very good reason fail to have representative attendance, and we think a careful perusal of the detail of good things being provided will bear out our contention.

## INDUSTRIAL NOTABILITIES

**H**ENRY BERTRAM, secretary-treasurer and director, The John Bertram & Sons Co.; secretary-treasurer, Pratt & Whitney Co. of Canada, Ltd., Dundas, Ont.; director, Niles Bement Pond Co., New Jersey; director, Canada Foundries & Forgings Co., Welland and Brockville, Ont.; director, Chapman Engine & Mfg. Co., Dundas, Ont.; was born at Dundas, January, 19, 1856, the son of John and Elizabeth (Bennett) Bertram.

HENRY BERTRAM

He was educated in Dundas, and entered his father's engineering business in 1871, becoming a partner in 1886, the firm name being then changed to that of the John Bertram & Sons Co. In 1901 the Company was incorporated, Henry Bertram becoming secretary-treasurer.

He married in 1881, Jennie Graham, daughter of Andrew Graham, of Dundas, the family consisting of four sons and two daughters.

Clubs and societies in which Mr. Bertram is more or less interested include the Welland, Dundas; Hamilton, Hamilton; Engineers, and Ontario, Toronto; Engineers, Montreal; Laurentian, Ottawa; and the A.F. & A.M., respectively. His residence is "Glenholme," Dundas, Ont.

productive end of the steel situation. Recent purchases have shown that buyers are only contracting for their most urgent requirements; the mills, however, are showing no uneasiness, as orders now on the books are sufficient to keep them operating at capacity for many months. For several weeks no change has taken place in price quotations, and it is almost conceded that the next movement will be downward, although the present situation appears to justify the maintenance of present prices for some time yet. Great activity is still shown in billets and sheet bars, the heavy export demand more than compensating for the slight falling off of domestic trade. The demand for all kinds of plates is very heavy, the requirements for shipbuilding being far greater than the mills can supply. Sheet mills are still unable to satisfy the demand, as many of them are booked for the remainder of the year. Owing to the constant drop in the price of spelter, it is expected that galvanized sheets will soon weaken. In some cases mills are insisting that buyers, who have no cancellation contract, must accept delivery of material at contract prices. The expected advance of wire and wire products has not materialized, and with the dull season coming on and a relatively light demand, further advance at the present time is now unlikely. Business in wrought iron pipe and boiler tubes continues very good.

**Metals**

The general market is quiet and inactive. With the exception of aluminum, which continues firm, the metals are inclined to weaken. Copper is firm but quiet. Tin is very quiet with the dull season approaching. Spelter continues to decline, with consumers showing little interest. Lead has become easier, and antimony is fast becoming normal. A comparison of present prices with those of a year ago and just before the war is here given.

	July, 1916	July, 1915	July, 1914
Copper .....	\$31.50	\$21.25	\$15.50
Tin .....	45.00	45.00	34.50
Spelter .....	15.00	26.00	5.25
Lead .....	8.50	7.50	4.85
Antimony ...	23.00	40.00	8.25
Aluminum ...	65.00	35.00	20.00

**Copper.**—Very little activity is being shown in copper at present, as the majority of consumers are apparently well covered for immediate requirements. Foreign demand is very light, and it is not likely that further heavy buying will take place for some time. Under these conditions it is expected that the surplus supplies from refineries will be sold to domestic users. As the producers' books are well filled with future orders, they will not require to urge the buyers to purchase excess metal, and it is not

## The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

**Montreal, Que., July 10, 1916.**—Throughout all branches of industrial activity the situation continues to be highly satisfactory. The manufacture of munitions is still the centre around which all other lines revolve, and from which they get inspiration. The outlook for a heavy grain crop is quite encouraging, so much so that it reflects favorably upon trade in general. One of the great problems, however, will be the securing of sufficient labor to successfully harvest what now promises to be a bumper crop. Bank returns continue to show the prosperous condition of the country, and latest figures show that the business failures for the past six months were much fewer than the corresponding

period of last year. Activity in the steel trade is as great as ever, a slightly easier undertone, however, being more or less evident.

**Pig Iron**

Very little change is noted in the pig iron situation. The demand is still heavy for steel-making pig; the market, notwithstanding, is a little easier. Pittsburgh quotations show a decline of 50c a ton for Bessemer and 25c for basic, present prices being \$22.45 and \$18.95 respectively. Foundry iron is quiet and quotations have declined from 25c to 50c a ton.

**Steel**

The middle of the year has been reached with no apparent relief in the

thought that any great change will be noted in price quotations until general conditions change considerably.

The situation in London is having a disturbing effect upon the market here, as the sharp declines recently noted are not taken as the correct tone under existing circumstances. However, the standard market is being carefully watched, as developments in the next few weeks may have great bearing on the metal situation. The week has shown a decline of £12 on standard spot; £11 on futures, and £3 on spot electrolytic; present quotations being £91 for standard spot; £89 for futures, and £129 for electro spot. New York quotations have become slightly easier, a decline of  $\frac{1}{2}$ c on lake,  $\frac{3}{4}$ c on electrolytic, and  $\frac{1}{4}$ c on casting, making the latest quotations 26 $\frac{1}{2}$ c, 26 $\frac{1}{4}$ c, and 24c per pound respectively. Local dealers are quoting a  $\frac{1}{2}$ c advance on a fair market, prices this week being 31 $\frac{1}{2}$ c for lake and electrolytic, and 31c for casting.

**Tin.**—The relative quiet spell now prevailing is expected to be followed by further dullness as the summer advances. The constant weakening of the other metals is causing the buyers of tin to keep out of the market in the way of heavy purchases, and they are apparently only covering themselves for their most urgent requirements. The feeling appears to be prevalent that the time is approaching when a readjustment of quotations will be necessary. Cable reports show a further decline in the London market, a drop of 15 shillings being noted on standard spot and £1 on futures and Straits spot. Latest quotations are: £173 for standard spot; £173 10s. for futures; and £174 for Straits. New York continues to weaken, the current price of 39 $\frac{1}{2}$ c showing a decline on the week of  $\frac{3}{8}$ c per pound. Local dealers report a very quiet market, with prices easier; a drop of 2c placing the present quotation at 45c per pound.

**Spelter.**—Following another break on the London market, spelter continues to show a demoralized condition. This panicky trend does not indicate the true tone of the present situation, however, and there appears little reason why the market should take such a slump at this time, for while weakness is no doubt evident, there is nothing to justify the heavy declines recently quoted. In face of existing conditions, and with the hope of steadying the market, several producers have withdrawn, and are refusing to quote prices until the situation has cleared. While prices are constantly declining, it is very doubtful if much metal could be obtained at quotations given. Recent advices from London show a drop of £17 on spot, and £12 on futures since last week, the latest price quotations being £44 and £41 respectively. Following the break in the London situation, New York has declined

2c on prompt Western shipment, the nominal figure being about 9 $\frac{1}{4}$ c per pound. Local dealers report a quiet market, with prices steady at 15c per pound, but showing an undertone of weakness.

**Lead.**—Following the recent strength of the market in face of irregular conditions, lead is now beginning to weaken, the present market being reported dull and easier, with quotations again on the decline. Production is very heavy, but no apparent accumulation of stock is shown by any producers. Concessions have been general of late, and these are likely to continue for some time. Weakness is shown in London, a decline of 15 shillings on spot, and £1 on future, placing the latest quotations at £28 and £27 respectively. Both the Trust and outside interest quotations have declined  $\frac{1}{2}$ c, with the independents slightly below the Trust prices; the former quoting 6.45c and the later 6.5c per pound. The situation here is quiet and unchanged, with prices easier at 8 $\frac{1}{2}$ c, a decline of  $\frac{1}{2}$ c per pound.

#### CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion \$100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

**Antimony.**—The weakness which has prevailed in antimony for the past month or so continues. The absence of further shrapnel shell orders and the possibility of only a further limited demand has gradually brought the market down to more normal condition. Present indications are that this metal will remain comparatively weak for some time. New York reports a further decline of  $\frac{1}{2}$ c, current prices being 16c per pound. The local situation is very dull, and dealers are quoting 23c, a decline of 5c on the week.

**Aluminum.**—The market is firm, with prices steady at 65c per pound.

#### Machine Tools and Supplies

Conditions are gradually becoming normal, the demand for shell-making equipment being more or less quiet. Orders for heavy shell machinery are still being filled, but delivery is much more reliable than it has been for many months. Domestic demand is light, but steady, inquiries promising some good business. The limitation of shrapnel shell orders has had the effect of placing on the market a number of small

tools for re-sale by previous makers of shrapnel. No appreciable decrease is noted in the demand for machine shop supplies, and all makers of auxiliary equipment are very busy.

#### Scrap

In the large steel consuming districts the situation is beginning to show signs of returning strength. Large purchases for heavy melting steel scrap have recently been made, and prices have advanced about \$5 per ton. Many of the large users, in addition to being well supplied with scrap, have large quantities of rejected steel and discarded shells on hand. Other grades of steel and iron scrap are also taking on activity, but scrap metals are a little weak. Local dealers report a quiet market, with prices easier. Old copper has declined from 1c to 1 $\frac{3}{4}$ c, present prices ranging from 15c for light copper to 18c for wire. Machine composition and turnings have declined 1c, being quoted at 14c and 12c respectively. Brass clippings are 1c lower at 13c per pound. Wrought iron pipe and stove plate are quoted at 10c, a decline of 1c. Heavy lead is  $\frac{1}{2}$ c weaker at 5c, while tea lead at 4 $\frac{1}{2}$ c is 1c lower. Following the slump in spelter, scrap zinc is quoted at 7c, a drop of 4c per pound. Aluminum is easier at 33c, a decline of 4c per pound.

**Toronto, Ont., July 11.**—Industrial conditions continue favorable as regards the volume of business but there is no improvement in the situation as regards the shortage of labor and raw materials. Manufacturers are being handicapped on this account and in addition have to pay higher wages which altogether will increase the cost of manufactured goods. The export business continues to steadily increase; more cargo space is now available at lower rates which will benefit trade considerably.

#### Steel

The steel market continues steady with a tendency to dullness, more or less seasonable. The export business continues heavy and the situation has been improved by the decline in ocean freight rates. Although the mills are sold up into the first quarter of 1917, there are indications that deliveries are improving. Prices are firm and unchanged with the exception of lapwelded boiler tubes which have advanced, as was expected. The situation in the tube market is unchanged and the prevailing prices will probably remain in effect for some considerable time, no further advance being expected. Wrought iron pipe is unchanged and steady. Many of the mills are well sold up for the remainder of the year on lapweld pipe, but on butt-weld sizes they can make

delivery in two or three weeks. The skelp situation is unchanged and prices are very firm. On wire rods, domestic mills are in a sold up condition while in the States the new demand is quiet as consumers are covered over the remainder of the year. The sheet market is quiet but prices are very firm with the possibility of an advance owing to the increase in cost of labor and sheet bars. It is expected that the output of sheets will be restricted during the hot weather, and this will have a tendency to stiffen the market, particularly as stocks generally are low. Prices of galvanized sheets are unchanged locally but are weaker in the United States owing to the decline in spelter. Consumers who have stock are waiting in the hope that spelter may decline still further.

In the United States the export buying of steel products has been large recently, making up in large degree for a smaller domestic demand, and also helping to sustain prices. The export business consists principally of Bessemer pig iron, open-hearth and Bessemer billets, steel bars for shells, tin plate, and other finished products. The unfilled orders of the United States Steel Corporation on June 30, stood at 9,640,453 tons, a decrease of 297,340 tons compared with those on May 31. This is the first decrease in unfilled orders shown by Steel Corporation since August 1915. Steel bars are quoted at 2.75c; plates, 3.25c; and shapes 2.50c, Pittsburgh.

#### Pig Iron

The situation in the pig iron market is unchanged although prices recently have exhibited a weaker tendency. The consumption of steel making grades continues heavy and foundry irons are in fair demand. Current prices which are unchanged are given in the selected market quotations.

#### Scrap

The market for old materials is quiet and quotations continue to have a weaker tendency, with declines in copper, boiler plate, rails, malleable scrap, wrought-iron pipe, and scrap zinc. Light copper has declined  $\frac{1}{2}$ c, crucible copper 1c, heavy copper  $1\frac{1}{2}$ c, and copper wire 2c per pound. Boiler plates, rails and malleable scrap are each down \$1.00 per ton, while wrought iron pipe scrap has declined \$2.00 per ton. Scrap zinc is 2c, and lead  $\frac{1}{2}$ c per pound lower. Prevailing prices are given in the selected market quotations.

#### Machine Tools

The situation in the machine tool market is unchanged. The active demand for tools for munitions plants continues and a number of good sized orders are pending for large-swing lathes, drilling

machines, etc. Deliveries are improving owing to better facilities for increasing production and a falling off in demand. Reports from the States indicate that machine tools are being quite extensively offered for resale by munition manufacturers which will throw a considerable amount of second-hand equipment on the market. The machinery offered however, has been used principally for shrapnel and small sized high explosive shells which are not in demand now to any great extent.

#### Supplies

Dealers report brisk business in machine shop supplies. Prices continue very firm and higher quotations on a number of lines are expected shortly. The supplies affected are composed principally of iron, steel or brass. A sharp advance was made in shellac recently owing to the scarcity and increase in price of gums which are imported from India. The British Government placed an embargo on gums which has tended to restrict the available supplies; the high ocean freight rates have also helped to raise prices. Linseed oil and turpentine are steady and unchanged, while resins continue high in price and in good demand, particularly for the cheaper grades used in shrapnel shells. Lower prices in white lead are looked for in some quarters.

#### Metals

The metal markets continue weak, and lower levels have been registered for practically all. A sharp decline of copper in London has affected prices locally and quotations are lower. The copper market is in a waiting condition with producers sold up and consumers fully supplied for some months in advance. The tin market is unsettled with consumers holding off in anticipation of lower prices. Spelter has declined following a break in London and the market is unsettled with little business being transacted. The "Trust" have lowered their price on lead and the independents are offering concessions which is further weakening the market. The antimony situation shows no improvement and quotations have again declined. The aluminum market is steady at unchanged quotations.

**Copper.**—Inquiry for copper for prompt and last quarter delivery continues small but steady. The market is weak in London, and has declined here also. Most of the large producers are still sold up so far ahead that they cannot accept orders for even small lots for early delivery, and the result is that small consumers who want copper are endeavouring to

come into the resale markets. The prospect for a peaceful solution of the American and Mexican difficulties has improved the outlook, but shows no reflection in the market. Quotations are  $\frac{1}{2}$ c lower and are nominal at 29 $\frac{1}{2}$ c per pound.

**Tin.**—The market has been comparatively inactive and prices continue to decline. The tin situation is affected by the decline in other metals, the tendency being to depress the market. Stocks of tin have increased but the demand continues light. Local quotations are lower and nominal at 45c per pound.

**Spelter.**—A decline in London has been followed by lower prices in New York where the market is weak and more unsettled than ever. Although the market is declining, consumers are not showing any interest; some producers are shading prices, while others have retired from the market. Quotations are lower and nominal at 14 $\frac{1}{2}$ c per pound.

**Lead.**—The "Trust" has reduced the price of lead to 6.50c New York but this is not being adhered to by some of the independents who are quoting as low as 6.35c to 6.45c for spot metal, and 6.25c to 6.35c for August shipments. The production of lead is stated to be heavy but there is said to be no accumulation of stocks in the hands of any of the producers. Lead is dull and lower locally, being quoted at 8 $\frac{3}{4}$ c per pound.

**Antimony.**—The dullness and weakness which have characterized this metal in the past few weeks are as acute as ever, but the market shows some sign of a reaction. Quotations are lower and nominal at 26c per pound.

**Aluminum.**—Supplies of this metal are rather more plentiful but the market is dull and quotations unchanged at 67c per pound.

**Solders.**—Prices of solders are lower following the decline in lead and tin. Guaranteed is now quoted at 28 $\frac{1}{2}$ c, and strictly at 26 $\frac{1}{2}$ c per pound.

#### BUILD SHIPS AT PRINCE RUPERT

M. P. COTTON, contractor, of Vancouver, and H. H. Hansard, solicitor for the G. T. P., have been to Prince Rupert, where they inspected the dry dock and shipbuilding plant. Mr. Cotton represents a shipbuilding syndicate, which, if satisfactory arrangements can be made, will lease the G. T. P. plant at Prince Rupert for the purpose of building freighters to be operated by the company. It is proposed to build the ships of steel, and it is understood that application has been made under the Government's legislation to aid shipbuilding, for assistance in the building of four of these ships, which will be about 5,000 tons each.

## Engineering

**Hamilton, Ont.**—The Oliver Chilled Plow Co. will build an extension to their plant here.

**Hamilton, Ont.**—The Victor Law Works will erect a factory here to cost approximately \$6,000.

**Toronto, Ont.**—Toronto Electric Light Co. will build a one-storey brick garage, in Scott street, to cost \$2,500.

**Toronto, Ont.**—The William Davies Co., will install a cold storage and ice plant at their packing house in this city.

**Transcona, Man.**—Construction on the elevator to be erected here by the Canadian Government Railways will begin shortly.

**Beauceville, Que.**—The foundry owned by Marcoux & Poirer was destroyed by fire recently, the loss being estimated at \$12,000.

**Copper Cliff, Ont.**—The Canadian Copper Co., will construct a sewage pumping station. Tenders will be received by the chief engineer of the company until July 15.

**Redcliff, Alta.**—The Redcliff Rolling Mills are installing a new furnace which will double the capacity of the plant. Machinery for making bolts and nuts will also be installed.

**Lindsay, Ont.**—The Canadian Government new small arms ammunition factory will be located here. The contract for the buildings has been let to Westinghouse, Church & Kerr Co., of New York.

**Toronto, Ont.**—The city architect has issued to the Hospital for Sick Children a permit for the erection on L'aplante avenue, near College, of a one-storey brick and concrete power house to cost \$9,000.

**Trail, B.C.**—The new sulphuric acid plant, the first of its kind to be erected in B.C., has been completed and will go into operation shortly. The plant which has been constructed by the Consolidated & Mining Co., will manufacture acid as a by-product from the fumes of the smelter.

**Quebec, Que.**—Price Bros. & Co., propose making important extensions to their plant. A new unit will be added to the newsprint mill, also additions to other plants which will increase the

company's production of sulphite and ground wood pulp to 25,000 tons and 55,000 tons per year respectively.

**Weston, Ont.**—Construction work has been commenced on the new Russell Motor Car factory on Eagle avenue. Footings for the new building are being put in and cars and other material are arriving daily. A long siding has been constructed into the property by the C. P. R. Company. It is expected that the building will be completed by October.

### TENDERS INVITED—AUSTRALIA

The following foreign trade opportunities are published for the information of Canadian manufacturers:—

Tender forms, specifications, incidents and drawings have been forwarded by D. H. Ross, Canadian Trade Commissioner, Melbourne, for equipment required by the Victorian Railways, Melbourne; the New South Wales Railways, Sydney, and the Postmaster-General's Department, Melbourne. (These tender forms are open to the inspection of Canadian manufacturers at the Department of Trade and Commerce, Ottawa.) (Refer File No. A-1919.) Tenders close at Melbourne on September 6, and particulars of the requirements are as follows:—

3 Phase crane motors and controllers, and one phase workshop motor and starter (as per drawings).

3 Dry grinding machines.

2 Beading and coping rolling machines.

2 Tube swaging machines.

It will be a two-storey brick structure, 300 feet square. The site comprises about 28 acres.

**St. John N.B.**—The Booth Fish Co., which has large interests on both the Atlantic and Pacific coasts, have taken over the plant of the New Brunswick Cannery at Chamcook, St. Andrews, and will operate it this year in a general fishpacking business. This plant was originally constructed by the Canadian Sardine Co., and cost over half a million dollars. Last year the works were occupied by the Lane & Libby Packing Co.,

who have transferred their interests to the Booth concern. The present holders are a wealthy corporation.

## Electrical

**Watford, Ont.**—A by-law will be submitted to the ratepayers shortly to raise \$10,000 to cover the cost of a hydro-electric installation.

**Woodbridge, Ont.**—Woodbridge Hydro-Electric Commission has decided to make an extension of its power lines to Maple, a distance of about five miles.

**New Toronto, Ont.**—It is announced that the Goodyear Tire & Rubber Co., will very soon commence building operations on the new plant to be erected here.

**West Lorne, Ont.**—The Village Council held a special meeting recently when a motion was passed authorizing the Hydro Commission to buy the necessary equipment for the plant here.

## Municipal

**Sault Ste. Marie, Ont.**—An extensive waterworks system is contemplated by the town council, which will cost over \$250,000.

**Lethbridge, Alta.**—The city council are considering the installation of a mechanical filter with a capacity of three million gallons per day. A by-law will be submitted to the ratepayers to authorize an expenditure of \$100,000 on the plant.

**Stratford, Ont.**—The city council, in a special session on July 6, passed the by-law for \$30,000 debentures to take care of extensions and improvements to the local Hydro-electric distribution system recently made. The money is to be procured from the Ontario Railway and Municipal Board.

**Woodbridge, Ont.**—E. A. James, county good roads engineer, has been engaged by the council to prepare plans of a system of water supply for the village. It is not likely that the people will vote on this question before January. The proposed system will cost about \$40,000, and will include mains, pumping station, filtration beds and standpipe.

## General Industrial

**Leamington, Ont.**—The Heintz Mfg. Co., propose building an addition to their factory here.

**Quebec, Que.**—The St. Lawrence Paper Bag Co., will build an extension to their factory at a cost of \$20,000.

**Winnipeg, Man.**—Charles Blair, of Stockport, England, manufacturer of surgical dressings, may establish a factory here.

**Guelph, Ont.**—Negotiations have been concluded whereby the Malt Products Co. of Canada, take possession of that portion of the Sleeman Brewery on Waterloo avenue. They will occupy practically one-half of the building.

**Toronto, Ont.**—Excavation work has been started on a reinforced concrete four-storey factory building which will be constructed for the T. Eaton Co. at the southwest corner of Bloor and Dufferin streets. The building is to be 65 by 100 feet, and will cost approximately \$45,000.

**Port William, Ont.**—At a cost of over \$700,000, the Grain Growers' Co., of Winnipeg, awarded a contract to S. J. McQueen, of this city for its new elevator to be constructed on the Port Arthur waterfront near the site of the Saskatchewan Elevator Co., now under erection. The building will be modern.

## Tenders

**Saskatoon, Sask.**—Tenders are being called until July 26 for a high pressure water main system.

**Halifax, N.S.**—Tenders will be received until Wednesday, July 19, 1916, for furnishing 2,800  $\frac{5}{8}$  in. meters and 300,  $\frac{3}{4}$  in., meters in accordance with the specification made by the city engineer. Further particulars may be obtained from H. W. Johnston city engineer.

**Toronto, Ont.**—Tenders will be received by the chairman Board of Control, City Hall, until July 18, for the supply and delivery of one overhead hand-operated traveling crane. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall. T. L. Church, Mayor.

**Toronto, Ont.**—Tenders will be received by chairman Board of Control, City Hall, Toronto, up to Aug. 1, for the supply and delivery of air brake equipment, step and door operating mechanisms, gears and pinions. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

**Toronto, Ont.**—Tenders for Examining Warehouse will be received until July 17. Plans, specification and form on contract can be seen and forms of tender obtained at the offices of Thos. A. Hastings, clerk of works, Postal Station "F," Yonge street, Toronto, Ont., R. L. Deschamps, Central Post Office, Montreal, P.O., and at the Dept. of Public Works, Ottawa.

**Toronto, Ont.**—Tenders for the erection of a court house at Sault Ste. Marie (separate tenders are required for the heating and ventilating and plumbing and electric wiring) will be received up to July 21. Plans and specifications can be seen at the office of the sheriff, Sault Ste. Marie, and at the Departments of Public Works, Ontario Parliament Buildings, Toronto.

**Toronto, Ont.**—Tenders addressed to the secretary-treasurer of the Board of

### ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

**International Purchasing Commission, India House, Kingsway, London, Eng.**

**French.**—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministère de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

**Russian.**—Col. N. Golejewski, Military Attaché, Room 904 Flat Iron Building, New York City.

Education, will be received until July 13, for iron fence, folding gates, metal ceilings, local telephones, steam fitting, plumbing, electric wiring, etc., in connection with midsummer repairs, sundry schools. Specifications may be seen and all information obtained at the office of the superintendent of buildings, City Hall, Toronto.

**Ottawa, Ont.**—Tenders will be received until July 21, for the construction of an extension of 200 feet to the existing wharf at Chandler, county of Gaspé, Province of Quebec. Plans and forms of contract can be seen and specification and forms of tender obtained at this Department of Public Works, Ottawa, and at the offices of the District Engineers at Shaughnessy Building, Montreal, Post Office Building, Quebec, and on application to the Postmaster, at Chandler, Que.

## Building Notes

**Toronto, Ont.**—The city architect has issued a building permit to the Campbell Milling Co., for a five storey warehouse to cost \$17,000.

**Montreal, Que.**—F. W. Stair, of Toronto, is credited with the intention of erecting here a \$700,000 theatre in the near future. The house, which will be for vaudeville, will be erected in St. Catharine street, near Bleury street, and work, it is said, will begin with a month or six weeks.

**Toronto, Ont.**—Bowles Lunch, Ltd., have purchased the north-east corner of Shuter and Mutual street, on which they propose to erect a large bakery, laundry and refrigerator plant. The site is 110 ft. by 35 ft. The new building will be two storeys and basement, brick, concrete and steel structure.

## Personal

**W. K. Jeffrey**, formerly manager of the Ottawa Car Mfg. Co. has joined the Lyman Tube & Supply Co., as sales manager, with headquarters in Montreal.

**Charles Hodgson Osler**, civil engineer of the Montreal Light, Heat & Power Co., Montreal died on July 8, aged 56. The deceased was born in Sheffield, England and came to Canada in 1872. He was well known as a locating engineer and in this capacity was with the C.P.R. and C.N.R. for some years.

**John Yttrup** representing L. A. Jacobsen of Copenhagen, Denmark, machinery importer, is in Canada on a business trip. Mr. Yttrup in the course of an interview in **Canadian Machinery** office stated that arrangements had been made for representing a number of machinery manufacturers in connection with their Russian business.

## Trade Gossip

**The Chapman Valve Co.**, Toronto, will supply a number of valves to the Metagami Pulp & Paper Co., for their new paper mill at Smooth Rock Falls, Ont.

**The Canadian Gasoline Corporation** have acquired the Canadian rights for the "Greenstreet" process for making gasoline. H. T. Bush, president of the Standard Ideal Co. of Port Hope, Ont., is a member of the syndicate.

**Windsor, Ont.**—As a reflection of Windsor's business growth, customs re-

## Bridgeford 9.2" Boring Lathe

A MACHINE of ideal proportionate strength. Stresses have been accurately calculated on this machine and all parts have been reinforced and strengthened and a liberal allowance made for a safety factor, superior material is used and you have the result—a smooth-running, perfectly balanced unit that ensures efficiency, economy, speed and results.

Illustrated above is a heavy duty, low swing Boring Lathe having a specially designed carriage with auxiliary hand feed for internal profile. Carries a 6" steel bar with male taper, allowing for light design of cutter heads; 3 automobile style speed changes, all hardened and running in oil bath. A chip tray is attached and used in conjunction with stationary lubricant tank.

Regular equipment comprises everything except chuck, steady rest and cutter.

Delivery in time for YOUR needs.

# A THREAD IS A THREAD

A Thread is a Thread to a Geometric Die Head—Long threads or short, heavy or light work, large diameters or small, fine threads or coarse—they are all alike to the Geometric Die Head.

Whatever the make of your Screw Machine, a Geometric Self-opening and Adjustable Screw-cutting Die Head can be furnished to fit it.

Take up your threading proposition with us. Get acquainted now, and when in need of Screw-cutting Tools, you will find a Geometric the friend, indeed.

Let us know the class of screw-cutting that interests you, and we will send booklet describing the type of tool that is best suited to it.

**The Geometric Tool Company**  
NEW HAVEN, CONN.

Canadian Agents:

Williams & Wilson, Limited, Montreal

The A. R. Williams Machinery Co., Limited, Toronto,  
Winnipeg, St. John, N.B.

turns for June show an increase of more than seventy-three per cent. over the same month last year, with the figures \$454,498, as compared with \$261,662.

**Sarnia, Ont.**—Customs returns for June of this year are the largest in the history of the port. The total receipts show an increase of \$61,803.48 over May, and are three times as large as for the corresponding month of last year. The leading article on which duty was paid, was coal.

**The British Board of Trade** has appointed a committee headed by Baron Farrington, chairman of the Great Central Railway, to inquire into the best means to meet needs of British firms after the war, and to prepare a detailed plan for financing such firms, especially with regard to overseas contracts.

**Merritt, B.C.**—Mining men are showing considerable interest in a molybdenite property located on Texas creek, in the Lillooet district. The property is owned by J. B. Perkins and A. Hautier of Lytton, B.C., who have recently given a bond on it to American capitalists for \$300,000.

**List of Contraband Extended.**—An additional list of articles of contraband is published in the Canada Gazette. They are asphalt, bitumen, pitch and tar, sensitized photographic plates and papers, felspar, talc, bamboo and electrical appliances adapted for use in war, and their component parts.

**The Foundation Company, Montreal,** has received two contracts from the Algoma Steel Corporation, Sault Ste. Marie, Ont. One is for the revision of the yard, including the engineering and constructing of three plate-girder bridges, and the other is for the construction of the foundations of two open-hearth furnaces and a gas producer.

**Council of Commerce.**—F. C. Armstrong, of the Canadian Exporters' Association has sailed for Canada on the Missanabie and will make a report on his recent tour of France and Italy. It is said that one outcome of the commercial congress to be held at Ottawa in October, arranged by Sir George Foster, will be the formation of a permanent Council of Commerce to act in an advisory capacity to the Department of Trade.

**Winnipeg, Man.**—In accordance with the Steam Boiler Act, an Order-in-Council was passed recently dividing Manitoba into 18 boiler inspection districts. A map has been prepared showing the districts, the boundaries of which are given below. A number of the inspectors

have been appointed, but in other cases the selected men have not passed the examination as yet. The inspectors will be paid according to the work done. The reason for the greater number is to obtain efficiency.

**Halifax, N.S.**—Before Justice Chisholm at Supreme Court Chambers on July 4, tenders for the Nova Scotia car works were received from F. B. McCurdy & Co., for \$153,000, and Nova Scotia Steel & Coal Company for \$152,500. J. R. Douglas and other shareholders in an affidavit stated that if possible that he would buy the property for the shareholders and would give more than the tenders offered. It was ultimately decided by all concerned to sell the property at auction July 26, the reserve price to be \$154,000.

**Will Build More Ships.**—Both the American and British interests which will be represented on the new board of direction of the International Mercantile Marine Co. favor a plan to build new ships out of earnings. Tentative plans under way call for the construction of a large number of ships out of the cash reserves of the company. Such a plan, it is contended, will mean more in ultimate gain for both the preferred and common stock than a hasty payment of back dividends on the preferred. No contracts have been let but it is proposed to build the new ships in England.

**Railway Directors Selected.**—Although there is as yet no official announcement, the following Government directors on the Board of the Grand Trunk Pacific and Canadian Northern Railways have, it is understood, been selected. On the C. N. R. board the directors will be Messrs. W. K. George, of Toronto; H. A. Richardson, of Kingston, and W. J. Christie, of Winnipeg; and on the G. T. P. board, Messrs. J. B. Fraser, of Ottawa; Jules Hone, of Montreal, and Peter McAra, of Winnipeg. There will be no announcement as to the personnel of the commission to be appointed to investigate railway conditions in Canada for some days yet.

**Russian Munitions Inspection.**—Munitions makers who have worked on contracts for Great Britain and Russia say that it is easier to make ten shells for England than one for Russia. The Russian inspectors are exceedingly hard to please, and reject shells, rifles, or other munitions for faults that seem often imaginary, or which, in any event, do not affect the usefulness of the article. For instance, one concern which is making rifles for Russia has had trouble because the stain failed to take quite evenly on some of the wooden gun stocks. A munitions expert attributes the difference be-

tween the demands of the inspectors of the two countries by suggesting that the British representatives are more highly trained men, and are, therefore, allowed more leeway in using their judgment when there is any question of failure to meet specifications.

**The International Paper Co.,** who propose erecting a 200-ton newsprint mill in Canada, was formed as a result of the consolidation of nineteen paper producing companies. The concern was incorporated in New York in January, 1898, and six other companies were taken in at a subsequent time. The various plants are located in Maine, New Hampshire, Vermont and New York States, eight being in Maine, and nine in New York State. They produce 1,200 tons of ground wood pulp per day, 400 tons of sulphide pulp per day and 1,700 tons of paper per day. In addition to its holdings of spruce woodlands in the United States, the concern has a considerable amount of land in Canada, and it has the license of the Canadian Government to cut timber on 3,000,000 acres of wood land in the provinces of Quebec and New Brunswick. The outstanding capital stock of the company is \$40,000,000.

**Liquid Air Research.**—Arthur L. Clark, professor of physics in Queen's University, who went to Holland at the invitation of Prof. H. Kamerlingh-Onnes, the famous director of the marvelous Physics Laboratory at the University of Leiden, to go further into the question of liquefying air, and who has just returned home, states that his mission was successful. The object of Prof. Clark's going to Leiden was to determine more accurately the temperatures at which air liquefies and freezes. At the Leiden University he liquefied and froze air. The results of the joint experiments of Prof. Clark and Prof. Onnes are to be published in the proceedings of the Royal Academy of Amsterdam and also in the report of the International Commission of Cold, of which Prof. Clark is a member. Prof. Clark states that Prof. Onnes is of the opinion that there will be a great commercial future for liquid air, and predicts that in a few years it will be extensively used in connection with the mechanical arts. Prof. Clark intends to install a liquid air machine at Queen's for the purpose of continuing his experiments.

## Marine

**New Toronto, Ont.**—The Village Council has decided to purchase a new pump for the waterworks system. It

# Mechanical Engineering Books

If you are desirous of improving yourself in your trade and so putting yourself in the position of making more money, these Mechanical Engineering Books will be found helpful.

**MACHINE-SHOP WORK.** By Frederick W. Turner, Instructor in Machine-Shop Work, Mechanics Arts High School, Boston. 208 pp., 241 illus. Cloth binding. The use of various hand tools is explained, followed by a comprehensive discussion of the lathe and lathe tools, with the methods of screw cutting, taper and eccentric turning, etc. The way to figure compound gears for screw cutting; drilling; boring; planers; shapers; slotters; milling machines and cutters; how to cut spirals, gears, cams, etc.; grinding; the operation of automatic machines. Price \$1.50

**MECHANICAL DRAWING.** By Ervin Kenison, S.B., Assistant Professor of Mechanical Drawing, Massachusetts Institute of Technology. 176 pp., 120 illus. Cloth binding. Gives a course of practical instruction in the art of Mechanical Drawing, based on methods that have stood the test of years of experience. Includes orthographic, isometric and oblique projections, shade lines, intersections and developments, lettering, etc., with abundant exercises and plates. Price \$1.00

**FOUNDRY WORK.** By Wm. C. Stimpson, Head Instructor in Foundry Work and Forging, Department of Science and Technology, Pratt Institute. 160 pp., 142 illus. Cloth binding. A practical guide to modern methods of moulding and casting in iron, brass, bronze, steel, and other metals, from simple and complex patterns, including many valuable hints on shop management and equipment, useful tables, etc. Price \$1.00

**PATTERN MAKING.** By James Ritchey, Instructor in Wood Working, Armour Institute of Technology. 160 pp., 250 illus. Cloth binding. Shows the reader how to take the blueprint and from it make the pattern for any kind of casting under any condition. The allowances for shrinkage, draft, and finish are explained. Simple and built-up patterns of all kinds are clearly treated. Various special cases are taken up, such as pulleys, cranks, pipe connections, valves, etc. Price \$1.00

**MACHINE DESIGN.** By Charles L. Griffen, S.B., Assistant Engineer, the Solvay-Process Co., American Society of Mechanical Engineers. 208 pp., 82 designs. Cloth binding. Explains in detail how to make the entire design of all kinds of machinery, how to lay out gears, etc., with complete specimen designs of numerous machines. Price \$1.50

**TOOL MAKING.** By Edward R. Markham, Consulting Mechanical Engineer, formerly Superintendent of the Waltham Watch Tool Co., American Society of Mechanical Engineers. Author of "The American Steel Worker." 224 pp., 325 illus. Cloth binding. Takes up the methods of treating tool steels—annealing, tempering, spring tempering, hardening, case-hardening, etc.; how to make drills and reamers of all kinds; the making of arbors and mandrels, taps, hobs, reamer and tap-holders, jigs, gauges, dies and die-holders of all kinds, counterbores, facing tools, milling cutters, hollow mills, and forming tools. Gives all necessary information for tool making in all its branches. Price \$1.50

**FORGING.** By John Lord Bacon, Eng. and Supt. of Construction, with R. F. Shields & Son, San Diego, Cal., American Society Mechanical Engineers. Author of "Forge Practice." 128 pp., 180 illus. Cloth binding. A working handbook of practical instruction in hammering, working, forming, and tempering of wrought iron, machine steel, and tool steel, including the important modern development of electric welding. Price \$1.00

Sent postpaid on receipt of price. We can also furnish you with other standard works on Engineering in all its branches, including books for Civil Engineers, Contractors, Electricians, Foundrymen, Steam Engineers, Mechanical Engineers, Municipal Engineers, Railroad Engineers, Sanitary Engineers, Gas Engineers, Hydraulic Engineers, Technical Men.

will have a capacity of 600 gallons per  
 minute.

**Bowmanville, Ont.**—A by-law has been  
 registered to authorize an expenditure  
 of \$9,000 for the purpose of completing  
 the waterworks and sewerage systems  
 now under construction.

**Smiths Falls, Ont.**—The Town Council  
 is starting an aggressive movement for  
 cheaper power in Eastern Ontario, and  
 an effort will be made to have the  
 hydro-electric system installed here.

**Port Dover, Ont.**—Plans have been  
 prepared by the Department of Public  
 Works for harbor improvements here  
 estimated to cost \$250,000. It is pro-  
 posed to establish a car ferry service.

**Toronto, Ont.**—The steamers Wah-  
 condah and Fordonian, lake freighters  
 of the Canada Steamship Lines, have  
 been requisitioned for the transatlantic  
 trade. Both steamers, which are Welland  
 Canal size, were constructed in Great  
 Britain within the past ten years. Since  
 their arrival in Canada they have most-  
 ly been engaged in the Upper Lake ser-  
 vice.

**Toronto, Ont.**—The Board of Control  
 have recommended, at the request of  
 General Manager E. L. Cousins, on be-  
 half of the Harbor Board, and subject  
 to the sanction of Finance Commissioner  
 Bradshaw, the authorization of general  
 debentures to the amount of \$1,500,000  
 to raise money to carry on the harbor  
 improvements. This is the balance of  
 the amount guaranteed by the city, the  
 amount already raised being \$3,500,000.

## Woodworking

**Deseronto, Ont.**—The large plant of  
 the Dominion Hardwood Ltd., manufac-  
 turers of woodenware, was totally  
 destroyed by fire last Sunday morning.  
 It was a new industry, and had just  
 commenced running at capacity. The  
 loss is placed at \$100,000, partially  
 covered by insurance. The company ex-  
 pects to rebuild immediately.

## Catalogues

ing a description and specifications covering the "S-C" feed water regulator also the generator and regulating valve. The illustrations show typical installations and sectional views of the generator and valve, half actual size.

"Vim" Leather Packings are described at length in a bulletin issued by the E. F. Houghton & Co., Philadelphia, Pa. The principal features covering the material and process of manufacture are dealt with fully together with sectional views for use when ordering these packings. Price lists are included for the various styles of "Vim" packings, check valves and plunger leathers.

**Spray Cooling System.**—The Spray Engineering Co., Boston, Mass., have issued bulletin No. 101, entitled "Sprays for Cooling Condensing Water." A general description is given of the "Spray" cooling ponds, including particulars regarding their economy, power requirement, cooling capacity and design of the spray nozzle, while results of tests are also included. The cuts show a number of installations at various industrial plants.

The New York and New Jersey Lubricant Co., New York, have issued a series of bulletins dealing with "Non-fluid Oil" and its various applications, more particularly for textile, saw mill, and wood-working machinery and ring oiling bearings. The benefits obtained by the use of this oil are set forth and the class of work for which each grade is best suited is stated. Copies of these bulletins may be obtained on application to Fred Smith, 24 King street, west, Toronto.

## FOR SALE

FOR SALE OR RENT — MACHINE SHOP with railroad siding. Box 208. Canadian Machinery. (4)

TEN TYPE "F" COOPER-HEWITT ELECTRIC lamps for sale—110 volts, 60 cycles, alternating current. Will sell at bargain price. Canadian Ingersoll Rand Co., Limited, Sherbrooke, Que. (2)

LATHE FOR SALE—ONE 30 x 17-FOOT Pond engine lathe, suitable for heavy shells; in good condition; \$1,500.00. A. B. Ormsby Company, Limited, Toronto. (2)

A BARGAIN FOR QUICK SALE 30 H.P. 10 x 14 engine; guaranteed in first-class working condition; drive belt included. Hamilton Whip Co., Hamilton. (1)

FOR SALE—SCREW-CUTTING LATHE, 14 FT. bed, 16-inch Imperial chuck, 24-inch Swing Countershaft. Apply Thos. H. Ruth, 314 Pearl Ave., Peterboro. (1)

FOR SALE—ONE DAVIS 4½" CUTTING-OFF machine; practically new; been used less than three months; very reasonable. Canadian Linderman Co., Ltd., Woodstock, Ont. (tf)

12-INCH HEAVY DUTY (CANADIAN CORPORATION) moulder; just used six months; also band saw, shaper, buzz planer, used two years. Apply W. A. Rumney, 36 Fuller Ave., Toronto. (28)

20,000 LBS. 5% GALVANIZED STEEL GUY wire. We can offer this wire at very attractive prices. Winnipeg Machinery Exchange, Sutherland and Gladstone Sts., Winnipeg, Man. (25)

1-2-SPINDLE SHAPER. WOOD TOP, JOHN Ballantyne, Preston, make. used two months. 1 Dynamo, 45 lights. Toronto and Hamilton Electric Co. make. Used five months. Good as new. Box 195, Jordon, Ont. (R.T.F.)

WE HAVE FOR IMMEDIATE DELIVERY ten No. 9 Bardons & Oliver turret lathes; code word "Cedar"; 2½" capacity; exceptional value; price moderate. J. B. Stone Tool & Supply Company, 24 Guelph Building, Detroit, Mich. (24)

FOR SALE—EXCELLENT PLANT FOR THE manufacture of electric passenger and freight elevators, patterns, drawings, blueprints, special and ordinary machinery and parts. We are instructed to offer this entire plant at a fraction of the cost. If you are looking for a splendid manufacturing proposition, write for particulars of this one. Winnipeg Machinery Exchange, Sutherland and Gladstone Streets, Winnipeg, Man. (24)

FOR SALE—ELECTRIC PLANT—1 CORLISS engine, 16 x 30; better 72" x 14"; 1 dynamo, 1,100 V., 60 K.W., alternating current; 1 dynamo, 500 V., 20 K.W., direct current; transformer, watt meters, shafting, pulleys, belts. All in first-class condition. Sold complete or in part. C. Zuffe, Exeter, Ont. (26)

## FOR SALE

Fox Monitor Lathe, 18" x 5' 6", 9-hole turret, cross feed, hollow spindle, 5-step cone; good as new. Plating dynamo, 6 volts, 250 amp.; used only a short time.

PENDRITH MACHINERY COMPANY  
970 Queen St. West, Toronto

## FOR SALE

FOR SALE — THREE HOLDEN-MORGAN threading millers; one arranged for nose threading; two for base threading. One base threader can be changed to 4.5, as it was reduced from this size. Also two Bertram wavers and groovers, and one Martin, all used for 3.3 shells. Canadian Linderman Co., Ltd., Woodstock, Ont. (27)

FOR SALE—5 CARLOADS MACHINERY steel, consisting of rounds from ¼" to 5", squares, flats, angles and channels. Also tire sections. Slightly rusted through being outside. Will move this entire stock at great sacrifice in price to someone who can take delivery of entire quantity at once. This is an exceptional offer. Box 210, Canadian Machinery. (1)

FOR SALE—NEW HAVEN, 60-INCH SWING Standard Engine Lathe—triple geared, 15 ft. bed, hollow spindle, cuts threads 1 to 12. Compound rest, countershaft, steady rest, wrenches, etc. This tool is in excellent shape and owner offers special bargain. Particulars from Winnipeg Machinery Exchange, Sutherland and Gladstone Streets, Winnipeg, Man. (24)

FOR SALE—McDOUGALL ENGINE LATHE 20" swing, 10' bed, complete with 20" 4-jaw chuck, countershaft, steady rest, face plate, gears, etc. This tool, we understand, has never been used; has been lying crated for about 5 years. We are having it cleaned and offer a decided bargain for quick sale. Winnipeg Machinery Exchange, Sutherland and Gladstone Sts., Winnipeg. (3)

## SITUATIONS WANTED

MECHANICAL ENGINEER OPEN FOR position as shop engineer or superintendent; Technical graduate; broad experience in design, construction and production; have practical experience in forging and finishing large and small shells; have highest recommendation for ability to handle men efficiently. Box 205, Canadian Machinery. (25)

MECHANICAL AND ELECTRICAL ENGINEER, 16 years' experience, plant layout and maintenance; expert draftsman; wishes change. Box 207, Canadian Machinery. (26)

POSITION WANTED AS SALESMAN, agent, or traveler, for mechanical goods, or machinery, by Chief Engineer, (Marine), thoroughly reliable, of good education and appearance. Box 209, Canadian Machinery. (3)

## REPAIRING

ALL KINDS OF MACHINERY REPAIRED, rebuilt and installed. W. H. Sumbling Machinery Co., 643 Yonge Street, Toronto, Ont.

## WANTED

Burned out Tungsten Lamps, late type, drawn wire, 25, 40, 60 and 100 Watts, 110 and 115 volts.

DOMINION TUNGSTEN LAMP FACTORY  
ST. CATHARINES, ONTARIO

## WANTED

WANTED—ELECTRIC TRAVELLING Gantry crane, span about 57 ft., clearance 50 ft., overhanging at one end; load 15 tons. State full particulars and price. Thor Iron Works, Limited, Toronto, Ont. (27)

WANTED — BERTRAM WAVING ATTACHMENT for 4.5 shells, with or without lathe. Also 18" or 20" turret lathe. Give full particulars and price. Bowes, Jamieson, Limited, Hamilton, Ont. (rtf)

When writing advertiser kindly mention that you saw his ad. in this paper.

## For Sale Cheap

1—Box Girder Type Overhead Hand Power Crane, 48' 6" span, 5 tons capacity; complete, less the Hoist. This is a good Crane for Foundry, Boiler Shop, Storehouse, Stone Yard, etc.

1—12" Single "I" Beam Overhead Hand Power Crane, 30' 10" span, 3 tons capacity; complete, less the Hoist.

1—10" Single "I" Beam Overhead Hand Power Crane, 23' 6" span, 2 tons capacity; complete, less the Hoist.

1—Brantford (Gas) Bake Oven and 4 Racks.

1—No. 5 High-Speed Hammer.

1—30" Hercules Drill, made by Cincinnati Bickford Tool Co.

2—Baker Type Vises.

1—Linderman 2-Spindle Boring Machine.

1—24" Drill, Bertram Company.

1—26" Drill, London Machine Tool Company.

1—Bowser 40 Gal. Varnish or Oil Pump and Tank.

# The Service

## Capacity and Convenience

of a Hendey Lathe will prove of vital importance to your tool room.

The "Hendey" is accurate in the highest degree and suited for the efficient use of watch tool chucks, stop chucks, relieving attachments, etc.

It has the best spindle construction in its taper journals, with annular bearings and automatic oiling rings, which make for accuracy of alignment.

It has automatic stop for carriage working in either direction. Has reverse for carriage, controlled from apron.

Wide range of threads and feeds through mounted gearing, with ability to make gear changes for additional threads and feeds without limit.

A card will get you full particulars. Why not mail it now?

# Canada's 72-Inch Reflecting Telescope Installation

By J. S. Plaskett\*

*The scope of astronomical research in Canada has been materially enlarged by this latest addition to its operating equipment. The 72-inch reflecting telescope installed in the new Observatory, Victoria, B.C., has the distinction of being the largest of its kind in the world. Its construction has been the work and study of two and a half years on the part of the Warner & Swasey Co., Cleveland, Ohio, and in the opinion of those competent to judge, the completed instrument is a masterpiece of engineering genius, enterprise and skill.*

**T**HE completion of the mechanical parts or mounting of the 72 in. telescope, and the near approach to completion and erection of building and dome for the telescope, have stimulated public interest in this national undertaking and render the present an opportune time to present a description of the mechanical features illustrated by recent photographs which show the meantime condition of the enterprise.

The mounting of the telescope was practically completed and it was temporarily erected in the factory of the makers, the Warner & Swasey Co., of Cleveland, Ohio, about the end of March last. Some finishing touches to one or two details, the holding of a formal reception and exhibition of the telescope, delayed by the absence of members of the firm until May 25th, and the fact

that the dome was not sufficiently advanced to offer protection from the weather, caused the postponement of the shipment to Victoria until the middle of June. The erection of the mounting will occupy some three months, hence occurring during the most favorable season, and should be completed by the early autumn.

The 72 in. mirror, which is 12 inches thick at the edge, has a hole  $10\frac{1}{8}$  inches in diameter through the centre, and weighs some 4,340 lbs.; is finished on edges and back and its front surface is now practically spherical. Before it can be made a paraboloid of revolution, the surface necessary to bring the parallel pencil of light from any celestial object accurately to a focus, it is necessary to prepare a large flat surface for the purpose of testing the paraboloid. It is hoped that this will be finished and the mirror completed as soon as the mounting is ready to receive it.

## The New Observatory

The road to the summit of Saanich Hill, the site of the new observatory, which is about seven miles north of Victoria, B.C., was completed early in the spring of 1915, by the government of British Columbia who contributed \$10,000 towards the purchase of the site and had agreed to build a road from the present main road to the summit of the hill where the observatory building was to be located. Although the first source of water supply was a failure this important question is now satisfactorily solved.

The concrete pier for carrying the telescope and the surrounding circular steel building whose wall serves to support the dome, was commenced last summer and is now completed except for some minor details which are delayed until the telescope arrives. One of the essential features about the building and

TELESCOPE MOUNTING TEMPORARILY ERECTED AT CLEVELAND, OHIO.

SHOWING TELESCOPE PIER AND TELESCOPE BUILDING FOUNDATION.

\*Of the Dominion Observatory, Ottawa, and head of the New Observatory at Victoria, B.C.

dome is that they are entirely of steel construction which allows them to rapidly assume the air temperature. They are provided with double walls and a system of louvres at the top of the dome ensuring a thorough circulation of the

The telescope is to be used in three different forms, observations being made at the prime focus, at the Newtonian focus and at the Cassegrain focus. In the photography of the heavenly bodies or in obtaining spectra of very faint ob-

at the side of the tube. In the Cassegrain form a convex mirror 19 inches in diameter placed about 7 ft. below the prime focus reflects the light back through the central hole of the main mirror to a focus below the mirror cell where it can be visually observed, photographed or analyzed by the spectrograph. The equivalent focal length of this combination is 108 ft. giving images of exactly the same size as a refractor with a tube 108 ft. long.

#### Telescope Mountings

The function of the mechanical parts or mounting of this or any telescope is to hold the optical parts invariably, and at the same time without flexure or strain, in their correct relative position, to enable them to be readily pointed to any desired object, and to move them as a whole accurately to follow the motions of the stars. It will be realized that mechanical and engineering problems of a very exacting character were encountered in the design and construction of this great telescope, when it is considered that the star image in photographing has to be held in one position on the plate within less than the thousandth of an inch, and that this image is formed by an optical combination with a focal length of 108 feet. In other words the enormous mass, nearly 45 tons, of the moving parts of this telescope must be so accurately pointed to and follow the motion of the star that the deviation of a line 108 feet long from the true pointing is less than the thousandth of an inch. The previous experience of the

STRUCTURAL STEEL FRAMEWORK OF TELESCOPE BUILDING.

air and the maintenance of the interior at the shade temperature.

A contract for the 66-foot revolving dome which in the case of a large reflecting telescope is a most important part of the equipment as it has to be provided with many accessories required in the handling of and observation with the telescope was awarded in May 1915, to the Warner & Swasey Co., so that dome and telescope were designed together and should work in proper relation to one another. This dome is now being erected on its building at the observatory site and although it has not yet been operated its temporary erection at Cleveland sufficed to show that it will be the most complete and convenient in every operating detail of any ever built.

One of the observer's houses is completed, but none of the other buildings required have yet been begun. This dwelling will enable the supervision of erection of dome and telescope and the preliminary adjustments and experimental work to be efficiently performed. It is hoped that by the time the telescope is in shape for regular and systematic operation the necessary building equipment will be provided.

#### Telescope Features

It may be of interest to give a summary of the main features of the telescope mounting at this time leaving a full account until its final erection and completion.

jects, the photographic plate or small spectrography may be placed at the upper end of the tube in the "prime focus" 30 ft. above the great mirror. In the Newtonian form a plane mirror 19 in.

DOMES TEMPORARILY ERECTED AT CLEVELAND, OHIO.

in diameter about 4 ft. down the tube and inclined at 45 degs. reflects the light to a focus on the plate or spectrograph

makers in the design and construction of the largest refracting telescopes in the world, the Yerkes 40 in., the Lick 36

in., and many others, has been of great value in this connection. Further, the great advances in recent years in the production of high grade steel castings, in the manufacture of bearings in which friction has been reduced to a minimum, and in other directions has enabled a telescope to be constructed which is not only considerably larger in size but is superior in design, in accuracy, and in convenience and smoothness of operation to any existing instrument.

The telescope, whose general form follows the English type of equatorial mounting and is well shown in the first photograph, has a long polar axis supported at its north and south ends by bearings, in a direction parallel to the earth's axis. The declination axis, to which the tube is attached at right angles, passes rectangularly through the central cubical portion of the polar axis, the weight of the tube on one side being counterpoised by the declination gearing and housing on the other.

#### Polar and Declination Axis

The polar axis is composed of three sections, all of the best steel castings, firmly bolted together, namely, the central cubical section above mentioned and north and south conical tubular sections. It is nearly 23 feet long and weighs about ten tons. The declination axis is a steel forging,  $5\frac{1}{4}$  tons in weight,  $14\frac{1}{2}$  ft. long by  $15\frac{1}{2}$  in. in diameter, with a flange 41 in. in diameter by 4 inches thick, to which the tube is bolted. The tube is also in three sections, the central cylindrical steel castings, about  $7\frac{1}{2}$  ft. in diameter by 6 ft. long, weighing 7 tons, being attached to the flange of declination axis; to the bottom flange of this central section is bolted the steel mirror cell, weighing with mirror counterpoises and mirror, 6 tons; while to its upper end is firmly attached the skeleton tube, a beautifully designed and extremely rigid piece of structural work, upwards of 23 ft. long by  $7\frac{1}{2}$  ft. in diameter, and weighing, with attachments, about two tons.

#### Spectograph and Visual Appliances

Below the mirror cell the spectograph and visual appliances for use at the Cassegrain focus are attached. At the upper end of the skeleton tube an exceedingly ingenious arrangement, avoiding the use of several heavy and awkward extensions of the skeleton tube, which

were necessary with all previous reflectors, enables either the prime focus, Newtonian or Cassegrain attachments to be used at will and with the minimum of trouble and delay in changing from one to the other.

The driving clock, similar in design to that which has been so successful in the Lick and Yerkes telescopes, moves the telescope in right ascension by means of an accurately cut worm-wheel 9 feet in diameter, mounted on the polar axis by ball and ball thrust bearings and clamped to it when required by an electric motor.

#### Telescope Electrically Operated

The telescope is moved from one position to another and set and guided whol-

ly by electric power, no less than seven motors besides several solenoids and magnetic clutches being required for these motions. The quick motion motors move the telescope at the rate of 45 degs. per minute, one revolution in 8 minutes, in both coordinates. The slow motions have two speeds, a fast one for fine setting at the rate of one revolution in 36 hours, and a slow one for guiding, one revolution in 720 hours or 30 days. With the Cassegrain focal length of 108 ft., the guiding speed of the star image at the focal plane is  $1/300$ th inch per second or  $1/5$ th inch per minute. The electric wiring and control systems have been carefully worked out, all sliding brush contacts avoided, and the whole system installed in a permanent and yet easily accessible form, giving the maximum of convenience in operation with the minimum of attention and repair. The method of operation will be as follows: An operator on the observing floor controls the quick motion and clamps of the telescope and the rotation of the dome from the most convenient of the switchboards, one on the east and the other on the west side of the south pier, the telescope being quickly set approximately to the tabular position of the desired object by the sidereal and declination setting circles. The observer at either the upper or lower ends of the tube can clamp or unclamp the telescope, make the fine settings and guide by means of push buttons located on a small keyboard which he can carry around with him or attach to any convenient place.

#### High Grade Workmanship

The mechanical workmanship throughout is of the very highest grade, such indeed being necessary for the proper performance of the required operations. The principal mechanical feature wherein it differs from other telescope mountings is in the main bearings, in the skeleton tube, in the accurate cutting of the driving worm wheel and in the extensive use of steel castings for the principal parts.

It has always been considered necessary hitherto by astronomers to have the alignment or collimation of the polar and declination axes determined by cylindrical journals and bearings and to reduce the friction on these sliding contacts by ball or roller relieving devices. The perfection of modern ball bearings has rendered this arrangement

unnecessary and the main bearings are wholly of the self-aligning ball form, the S.K.F. Swedish bearing. The friction is thus much reduced and a very slight pressure on the tube is sufficient to set it in motion. The amount of current consumed in moving the telescope in quick motion would only be sufficient to light one 16 c.p. incandescent lamp.

#### The Skeleton Tube

The essential features about the skeleton tube are its lightness, its great stiffness and the new method of interchanging the attachments at the upper end. It is built up of ordinary structural mem-

SHOWING DOME, ETC., OF TELESCOPE BUILDING,  
MAY 5, 1916.

ly by electric power, no less than seven motors besides several solenoids and magnetic clutches being required for these motions. The quick motion motors move the telescope at the rate of 45 degs. per minute, one revolution in 8 minutes, in both coordinates. The slow motions have two speeds, a fast one for fine setting at the rate of one revolution in 36 hours, and a slow one for guiding, one revolution in 720 hours or 30 days. With the Cassegrain focal length of 108 ft., the guiding speed of the star image at the focal plane is  $1/300$ th inch per second or  $1/5$ th inch per minute.

The electric wiring and control sys-

bers the stiffness being given by diagonal steel tension rods which are screwed up sufficiently tight so that they are always under tension, even the lower set when the tube is horizontal. The interchanging of the Newtonian & Cassegrain mirrors at the upper end of this tube previously accomplished by fitting each into a separate extension of the tube thus entailing the handling of awkward and heavy pieces has been much simplified in this telescope by leaving the tube full length and devising a simple means of interchanging the mirrors only. Less than one-quarter the weight has to be handled, it can be done in one-tenth the time, and with no danger of accident.

The worm wheel which is 9 ft. in diameter with 720 teeth cut in its bronze rim was mounted on a rigid stand on its own ball and ball thrust bearings and each tooth cut by a cutter set at the proper angle. The spacing was done by means of a circle 42 in. diameter graduated on silver to half degrees by the Warner & Swasey circular dividing engine whose greatest error is six tenths of a second of arc. This was concentrically mounted on the worm wheel and the settings made by two micrometer microscopes. The teeth were cut around three times to remove any error due to springing and the previously lapped worm and the worm wheel were finally polished together by running them for several days with rottenstone and oil.

The three sections of the polar axis, the declination sleeve, the central section of the tube and the mirror cell are all steel castings heat treated. They were cast and machined at the Bethlehem Steel Works and are striking examples of the perfection to which the process has attained. They are entirely free from blow holes or other defects and as tough and homogeneous as forgings.

I desire to place on record my appreciation of the spirit which has governed the Warner & Swasey Co., in the design and construction of this great telescope. Their ideal has been to make this instrument the most accurate, perfect running and convenient of any ever constructed and to that end no pains or expense have been spared. When to this determination was added their unequalled experience in the design and construction of large telescopes, and their unrivalled facilities for producing the highest grade of workmanship the result cannot fail to be, and undoubtedly is an instrument of the greatest accuracy and one in which every needful and desirable movement or attachment is provided in the most simple and direct way.

The cause of astronomical research in Canada is to be congratulated that this great addition to its equipment was entrusted to such capable and sympathetic

hands and that this magnificent instrument has been so promptly and adequately completed.

### THE WAR AFTER THE WAR

THERE was a unique gathering of shipping and commercial men at the Mansion House, London, on June 21, to hear an address—the last but one before he returned to Australia — by Premier Hughes, on Empire trade now and after the war. The Lord Mayor of London (Sir Charles C. Wakefield) presided, and the meeting was organized by the British Empire Producers' Organization.

Mr. Hughes said that the Paris Trade Conference, from which he had just returned, had given official recognition to the great fact that between national welfare and national safety and trade relations there was a relation so intimate that it was impossible to treat them separately. It would have been well if that great principle had been recognized earlier, for it was certainly true that owing to our failure to recognize it, Great Britain had escaped national disaster almost by a miracle.

It was well that our people should be reminded of the peril they had thus escaped, for there were many in Britain still opposed to such changes, and who spoke still about returning and renewing those friendly connections with Germany after the war. However, those who were present at the meeting, did not intend that they should be renewed, and he believed that an overwhelming majority of people in Great Britain agreed with them.

### National Welfare vs. Personal Profit

They had to face the question of national welfare against mere personal commercial profit. What could it profit a nation if it gained the whole world and lost its own soul? They could only make themselves great and free by making themselves safe, and the first thing they had to fight was not Germany, but the German agents in Britain, those people who were acting as caretakers to the interests of Germany during the war, so that the Germans after the war could come back and find a jumping off place from which to fatten on the vitals of Britain, a policy they had pursued with such tremendous success during the last 25 years. Unless they fought those people with resolution, and all together, they would not win the war.

The first thing they had to do was to show their approval of the Paris Conference resolutions, and insist upon those resolutions being carried out. Those resolutions formed a great treaty between 600,000,000 people, of which half were white people. It was the only great alliance ever made in the history of the modern world. By doing their duty in that way they would not only

gain economic independence, but get for the world a perfect peace.

### Organization of Industries Urged

Mr. Hughes went on to urge an organization of British industries, raw material, and labor, for the industrial problems arising after the war, unless fully met, would be greater than the problem of the war itself. The Central Powers were organizing and we had to do the same, not only to fight their competition after the war, but the competition of neutrals, who would otherwise capture the carrying trade of the world. They had to find a man whose function in regard to industry would be like that of a lockkeeper on the Thames, letting in or out of Great Britain what was best for the interests of the nation.

They were determined to have the control of British industry in the hands of the British people. All those valuable lives were not to be poured out in vain, and they must not tamely submit to slip back into the economic maw of Germany. He believed the British Government would help the Empire in the great task of inter-Imperial trade relations by adopting the scheme for providing the spelter requirements of Great Britain from the concentrates produced within the Empire, which he had had the honor to lay before the government the other day. He hoped the Government would also adopt the scheme put forward by the British Empire Producers' Organization to produce all the sugar we needed in the Empire, and stop the supply of beet sugar from Germany.

Let them all vow to regard the great work of national organization as a sacred duty, holding its heaviest labors as a glorious privilege, for upon the success of their efforts rested not only the future of Britain but of the entire British race.

### BRITAIN AND RUSSIA

A. PROTOPOFF, vice-president of Russian Duma, a prominent personality, and one of the biggest textile producers in the country, in an interview relative to commerce, says: "I am absolutely certain that Britain and Russia will come to closest terms. We need English capital to enable us to fully exploit the reserve forces of our great country. The demand from some quarters that all invested capital shall be entirely under Russian control and only Russian engineers and workmen employed is nonsense. We shall, for many years to come, look to England to supply us with managers, directors, and engineers, and also, in many cases, with skilled workmen. The best means of inter-communication in business matters would be by means of a Business Bureau which would set about the formation of bona-fide Chambers of Commerce.

# PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data  
and Ideas Evolved from Actual Practical Application and Experience

## DESIGN OF LATHE, PLANER, SHAPER AND SLOTTER TOOLS—I.

**T**HE present article is the first of a series which, in addition to discussing the design of lathe, planer, shaper and slotter tools, will designate the factors which decide what shape tool will prove most efficient for any given cutting operation; indicate the ideal tool to use when a certain combination of factors is known, and explain the effect that variation in these factors has on the shape of the tool. The data is courtesy of Alfred Herbert, Ltd., machine tool builders, Coventry, England.

It is a curious fact that we are usually content to accept the ordinary, everyday things of life without ever pausing to consider whether or not they can or should be improved. To nothing in modern machine shop practice does this apply with more force than to the design, manufacture, and use of lathe, planer, shaper, and slotter tools. It has however, been proved over and over again relative to these that it is well worth taking time and trouble to get an absolutely clear and complete knowledge of all the factors necessary to attain any desired result in order that we devise the most efficient means for achieving our object. For any operation, no matter how small or trivial it may be, there is one method and one set of circumstances which are more favourable to the satisfactory carrying out of that operation than any other. It is only fit and right then for us to set ourselves to the determination of that environment which will render every operation carried out in our shops as efficient as possible.

### Progressiveness Everywhere Apparent

To-day we are not content with the methods of the last generation; we are not bound by the traditions of ten years ago, nor even of last year. We are constantly improving our methods, our processes and our plants. We inquire into the credentials of our previous practices and test them by theory, which in turn we prove by experiment. The whole trend of modern machine shop practice is to probe down to essentials, to find out the "why and wherefore" in every act of our business lives.

Our progress in this direction has gone further in some things than in others. The proper provision of efficient lathe and similar tools is one of the details of modern machine shop prac-

tice that has not yet received the attention it deserves. Most of the existing literature on the subject of cutting tools is a mere recapitulation of past and present practice, and makes no effort to prove that the tools and methods described are better than any others. Many works' managers have felt, subconsciously perhaps, that present methods could be improved, but have not the time necessary for a satisfactory elucidation of their difficulties.

No apology is offered therefore for laying down some definite rules on tool making, particularly as these are the result of much thought and experimenting on the part of men whose time is entirely devoted to the subject.

### Tool Forging

The whole underlying idea in the following remarks is that the most efficient form of tool shall be made and main-

FIG. 1. DEFINITION OF TOOL PARTS.

tained in the cheapest manner. Most treatises on the subject take it for granted that tool grinding and re-grinding are lengthy and laborious operations. They therefore devote the greater part of their remarks to the question of tool forging, which is to be done in such a manner that subsequent grinding shall take as short a time as possible. Forging is at best a rough and ready, inaccurate and inefficient process, and if, without detriment to the tool, it can be largely eliminated, we have reached one stage in our progress towards efficiency.

It is sometimes claimed that tools should be forged because the cutting properties of the steel are thereby improved. This may conceivably be the case with steels of poor quality, but is certainly not true of any recognised brands of high speed steel. On the contrary, there is always considerable risk that the steel will suffer through being worked at too low or too high a temperature.

By the Lumsden method, the shaping of the tool is done in the majority of cases by grinding instead of forging. This grinding, which is done dry before hardening, has been proved to have no deleterious effect on the steel, nor is it conceivable how intelligent grinding could possibly cause any injury. If, therefore, by means of grinding, a tool can be made to a definite predetermined shape in a fraction of the time required for forging, we cannot afford to close our eyes to the advantages such a process offers.

These are the lines on which the designer of the Lumsden Oscillating Tool Grinder proceeded in devising a machine which would ensure an adequate supply of correctly shaped tools at a low cost. The Lumsden Oscillator has been on the market for some four or five years. During that time much valuable experience has been gained and a vast amount of experimenting has been done with the result that the Lumsden system now offers the most economical method of making cutting tools for lathes, planers, shapers and slotters, also flat formed boring cutters, flat drills, and blades for inserted tooth milling cutters.

The accumulated experience of the last few years is incorporated in a chart which is furnished with all Lumsden Oscillators. This chart contains full particulars of a complete set of standard tools suitable for the average machine shop. It will be found that the tools suggested are of the most efficient shape for any ordinary machining operation and that the method of their manufacture is the cheapest and quickest in existence.

### Tool Design Concentration

Those who have given the whole question of cutting tools their careful consideration have come to the conclusion that tool design is an immense and important subject that well repays any time and trouble spent upon it. If every lathe, planer, shaper and slotter operator were allowed to design or control the design of the tools he uses, there would be such a multiplicity of tools in the shop that confusion would be inevitable, and the result would be inefficiency, reduced output, increased power charges and considerable waste of time.

It behoves those in authority therefore to tackle the tool problem in real earnest. The first item in the programme is to carefully consider the machines which

use tools of the lathe type and the nature of the operations performed thereon. Using in the first place the experience of other people—and we trust the remarks contained in this article will be of use in this connection—supplemented, when necessary, by experiments of their own, those who desire to revise their tool system will soon realise the necessity of a set of standard tools applicable to every machine and every operation concerned. They will also see the desirability of making such a set of standard tools as small as possible, yet with enough flexibility to cover every requirement.

When we use the term "Standard Tool," we do not mean a tool of fixed and unalterable shape, because according to the nature of the operation on which it is to be used, two or three variables will enter into its make up. A standard tool is one with a standard profile, but the rake of the top face, the radius at the cutting point, the inclination of the cutting edge to the tool shank, and the clearances of the cutting sides should be varied to suit the machine, the material being machined, and the nature of the cut.

None of these variables, however, need affect the decision to lay down certain standards; they merely influence the question of flexibility in suiting the standards selected to the needs of the shop.

#### Definition of Tool Parts

Before proceeding further with our enquiry into the tool problem, it is desirable to define the terms used to designate the various parts of a tool. See Fig. 1.

A tool consists of the shank and the nose, and unless otherwise stated the shank will be presumed to be rectangular.

The base is that side of the shank

Rake is the angle at which the top face is presented to the work. It is usually a combination of side cutting angle and front cutting angle, though it may in some cases consist of either of these separately.

The profile is a plan view when looking at the top face from a point at right angles to the base. It is determined by combination of the side and front angles, and the radius of the cutting point.

Clearance is obtained by grinding away that part of the tool nose which would otherwise rub against the work during the cut. According to whether

The general tooling is shown in Fig. 1. The first operation consists of facing the case, turning the body and diameter of flange to gauge, producing thickness of flange and bevel by means of the formed cutter shown on cross slide. The case is cut to length at the same time by means of a suitable cutter attached to the tail-stock spindle, and operated by the pilot wheel on tail-stock.

The case is next drilled. This must be done with care, as the primer hole may not show more than .004 eccentricity, which is measured by means of an indicator gauge reading in thousandths of an inch. The drill has three steps,

FIG. 2. REAMER AND STOP.

it is measured from the front or the side of the tool nose it is called front clearance or side clearance.

The radius of cutting point is the amount the corner between the front and side angles is rounded off.

In determining a set of standard tools we must take into consideration the three elements profile, clearance and rake.

#### MACHINING 3 IN. RUSSIAN SHELL CARTRIDGE CASES

by R. K. Douglas

AFTER the cases are headed and tapered, the first step consists of inspecting for scratches, dents, or other defects, which might cause rejection after machining. Owing to the depth of the in-

which rough form the primer head, body and flame hole, leaving .010 ins. to finish by reaming on diameter.

The primer hole is next rough tapped. An M.E.C. collapsible tap used, gives good results, leaving from .015 in. to .020 in. to finish by means of a hand tap. The tap must be in alignment with the spindle of the machine, or a tapered hole will result; leaving not enough stock to clean with the hand tap at the top, and too much at the bottom of the hole, thus possibly spoiling the case. There are seven full threads .14 pitch, Whitworth Standard, 1.070 in. dia. The machine is slowed down from 900 r.p.m. to 220 r.p.m. during this operation. The case is next recessed to clear the hand tap, and allow the last thread to be finished off nicely. The tool has only one

FIG. 1. GENERAL TOOLING LAYOUT FOR MACHINING THE 3-IN. RUSSIAN CARTRIDGE CASE SHELL.

which bears against the support that takes the pressure of the cut. The top face is that which takes the friction of the chip as it is cut from the work.

dent and small working limits allowed, the machining becomes a rather delicate operation, as compared with the 18 pdr. or 4.5 shell cartridge cases.

cutting point, because it does not finish the bottom of the indent as in the 18 pdr. case.

Following the above, the case is ready

to ream, which operation finishes the primer hole as far as the machine is concerned. The reamer cuts the primer head counter-bore to diameter and depth, the diameter of points of thread, depth of primer hole, diameter of primer hole below recess, cuts angle or chamfer on top of flame hole, reams flame hole to size, and chamfers top thread of primer hole.

The depth of the primer hole and the head counterbore is regulated by means of a stop attached to the reamer,

ed by the pilot wheel in the same manner as the cutting-off operation. The case projects from the chuck about 3 inches, and as it has to be polished  $2\frac{1}{4}$  inches from the flange, the operations of boring and cleaning are performed at the same setting.

The polishing is done by means of a felt wheel of proper width having emery or aloxite, glued to the face, and running in suitable bearings attached to the cross slide, the drive being had from the machine countershaft. The

it is often found that a lot of stuff, such as cuttings, files, scrapers, chisels, etc., accumulate about the machine in various places, and while necessary at the time, may not be required for the immediately following job. It is therefore advisable to clear the machine of all tools or other material, clean the cuttings and dust from the various slides, have tools sharpened and ready, so that when the next job is received, everything is in readiness to commence operations. Even when work is in progress, care should be

THE 3-IN. RUSSIAN SHELL CARTRIDGE CASE.

which, being set to the proper position, governs the depth independent of the stop on the turret slide. This stop serves a two-fold object, viz., by bringing it in contact with the face of the case, the proper depth is assured; it likewise does away with scraping the burr which is thrown up by the reamer, thus saving time and labor on the part of the operator, which naturally tends to increase production.

Referring to Fig. 2, the stop consists of a tool steel sleeve fitted with a lock nut for adjusting depth and attached to the reamer. The surfaces that act as a stop extend below the cutting edges of the reamer, and smooth out the burr. The part of the burr which is thrown below the diameter of the hole is removed by the reamer, leaving the corner smooth and square. It is essential that the contact surfaces be very hard and smooth, or trouble will result from the stop picking up pieces of metal and causing score marks. Two bearing points are required opposite each other. The stop should be left slack on the reamer for if it be held tight by set screws it is liable to chatter. This applies also to 18 pdr. and 4.5 in. cases.

The case is now transferred to another machine and bored at the muzzle. The extension (a) Fig. 1, is left off, and replaced by a bushing at the back of the spindle. This is a snug fit, so as to hold the outside diameter of the case to size, as it is apt to be expanded if not supported when the boring tool gets slightly dull. The boring tool is attached to the tail-stock spindle and adjust-

wheel is brought in contact with the case with the right hand, the left hand operating the pilot wheel on the inward cut of the boring tool. With the wheel left running on the case, the operator's attention can be given to the outward cut which smooth finishes the bore. This operation, including setting work, machining and removing when finished takes about 25 seconds.

The cases afterwards go to another department to be hand tapped, after which they are given a final inspection, all gauge points being inspected, and each case tried for contour in a gauge, which is a duplicate of the gun breech. After being examined for visual defects they are stamped, cleaned and lacquered; being then ready to pack for shipment.

### CLEARING DECKS FOR ACTION

By J. R. H.

WHEN ships are about to enter an engagement, one of the first orders issued is "Clear Decks for Action". This is absolutely necessary to the successful operation of the guns and other equipment; only the material required is permitted to be about, and that is kept in its proper place, and at such a point of convenience that the least possible effort will be required to apply it.

When a machine operator has completed a certain piece of work, and before he starts upon a fresh job, it is good practice to "Clear Decks for Action", so to speak. While performing some job,

taken that the machine, especially the movable parts, does not become littered with unnecessary material, which at any moment might interfere with the proper action of one or another of the moving parts.

Some few years ago, while working in a shop across the border, the importance of this was made clear to me by an experience we had one night, when the operator next to me met with a misfortune, caused by the dropping of a chisel from the saddle of his lathe onto the ways. The job he was working on was boring and threading a large housing nut, 30 inches long, 8 inches in diameter and  $1\frac{1}{4}$  inch pitch. Everything ran along smoothly until about midnight, when the boring bar, which was held between the centers, was seen to drop from its position. After shutting the lathe off, investigation showed that a large chisel had fallen from the saddle onto the ways of the lathe, becoming wedged between the saddle and the tail stock, and as the saddle was moving backwards, the tail stock was shoved back allowing the bar to drop.

Little damage was done fortunately, and the trouble was soon remedied, but along about three in the morning the same thing again happened, with more serious results; the thread was nearing completion and as the bar dropped into the nut the threads were somewhat torn. Luckily, the lathe was stopped in time, and the damage was not sufficient to necessitate the scrapping of the nut. The operator however has received his lesson,

and needless to say he is now very careful to remove all material that might cause a repetition of a like trouble.

## FIRST PRINCIPLES IN THE USE OF CORES.

By D. A. Hampson

**T**O the person uninstructed in foundry practice, the subject of "cores" is shrouded in mystery—a state of mind intensified by the somewhat gruff way in which one's patterns are turned down by the foundry foreman because of lack of cores and by the reticence in volunteering any information that will enlighten.

Very little work that requires the use of castings, either iron, steel, brass or aluminum, but necessitates the use of cores as well. Fundamental principles of cored work may be acquired by a beginner with a little study; these being all anyone needs unless he is actually engaged in the mechanical trades. If the beginner has mastered the rudiments of pattern work in its relation to the foundry, he will have little trouble in understanding core work. Briefly, a pattern makes a space in the sand mould that is filled with molten metal which, cooled, becomes the casting. This casting will be (except for shrinkage and defects) of the same size and shape as the pattern and will be a solid mass of metal. Now it is evident that if some piece, say a rod, were stuck through the center of the mould before pouring and could be withdrawn after the metal had cooled, a hole would have been formed in the casting. This hole would be a "cored hole" and the rod that formed it would be a "core". All cores are but this same thing in varied and more complicated form.

Taking a concrete example, consider the casting, Fig. 1, that is required to have a rectangular hole through it. The pattern would be made, as Fig. 2, of the same size and shape as the casting, but solid, and at the ends where the mouth of the hole is to be, a block is added of the same cross section as that of the hole required, and of a length depending on the size of the casting—an average length might be one inch. These blocks, one at each end, are called "core prints" or just "prints".

Their function is to form a print or depression in the sand mould that will locate and support the core itself. Fig. 4 shows the depression in the mould formed by the core prints; likewise the larger space which the pattern proper has left. The other "half" of the mould contains no print, simply a depression left by the pattern beyond the surface of the prints.

Cores are made of sand, flour, glue, and molasses in various proportions according to the class of work. They are shaped in a mould and baked in an oven until they are hard, after which they are ready to take their place in the sand mould. Cores are formed in a mould called a "core box" usually made of wood, the box having the size and shape of the hole in the casting plus that of the prints on the pattern. (In all that has been and will be said, it is assumed

shape long enough to get into the oven for baking.

A mould with the core set will be seen at Fig. 5. This view shows a core in place, and incidentally how a pattern may be bulky and solid while the casting produced may be extremely light and anything but solid. The hot metal after pouring disintegrates the materials of the core, and what remains of it on the finished casting is cleared off just as is the adhering moulding sand.

ILLUSTRATING FIRST PRINCIPLES IN THE USE OF CORES.

that the reader knows that due allowance has to be made for the shrinkage of metal in cooling.) The core box for the casting, Fig. 1, is shown at Fig. 3. The space formed by the rim around the under board is measured in accordance with the rules just related. It is filled with the plastic core mixture level with the top, and the box is then inverted, dumping the core out. From this latter the shop name of "dump box" is derived. Dump boxes are simple and cheap and answer very well for plain work. The core mixture, though plastic, is sufficiently stiff to retain its

Cores which are symmetrical are very often made in half boxes, that is—the face of the box is the center place of the core, and the depression is one half of the core. Two half cores are made in the box and are pasted together before baking. Fig. 6 shows such a half box, and illustrates as well another important point. In this case, the casting is to have a cylindrical core through it but the diameter is to be of two sizes—small at each end and larger inside—forming an interval chamber. Such a core is called a "chamber" core. Its applications are numerous. Generally, when it

is desired to have a bearing for a shaft at the two sides of a casting with a clearance space through the center—a chamber core is used. In Fig. 6, the length of the casting is from (a) to (a).

An outside core is a slight digression from the fundamental idea of a core in that it produces a "hole" on the outside of a casting. The portion of a casting, Fig. 7, shown inverted, is one leg of an iron topped table that has a projecting rim around the top and a foot at the end of the leg. While there are various ways to make this, the inexperienced person would do well to use an outside core making the pattern and its print as in Fig. 8. The construction of the core box will suggest itself if the general idea of those previously described has been comprehended.

Cores are second in importance only to patterns themselves. One of the highest developments of core work may be seen in the block castings for six and eight cylinder motor car engines. Taken throughout, the subject of cores is full of interest.

## FUTURE TRADE POLICY

THE accusation is sometimes brought against our Chambers of Commerce, Manufacturers Associations, Boards of Trade, and kindred bodies, that, while they pass many excellent resolutions from time to time, urging the Government to take steps with a view to maintaining an increasing trade after the war, they have not formulated any precise proposals as to the manner in which these objects are to be brought about. It might perhaps be pleaded on their behalf says a writer in the *Liverpool Journal of Commerce* that it is outside the province of Chambers of Commerce etc., to do more than indicate broadly the policy which in their opinion should be adopted, and that it should be left to the Government to devise the means of carrying their recommendations into effect. It is surely obvious, however, that business men must be the most competent judges not only of the best policy to pursue in the interests of British or Empire trade and industry, but also of the machinery best adapted to carry that policy into successful operation. The London Chamber of Commerce has brought forward certain definite proposals for meeting the trade problems of the war, and being in the direction above indicated, it should receive the careful and favorable consideration of the Government.

In February last, the London Chamber of Commerce passed a resolution in the following terms:—"That the Government shall render impossible a return to pre-war conditions by considering the question of preference between

all parts of the Empire and Allied countries, the favourable treatment of neutral countries, and the regulation by tariffs or otherwise of trade relations with enemy countries." The Chamber has now taken a further step forward, and has shown how the objects named in the resolution can be carried into effect.

The executive council has adopted a report of the Special Committee on Trade during and after the war, which states that the committee have considered the best methods of giving effect to the recommendations of the above resolution, and are of opinion that they can be largely carried out by means of a tariff. Practically no objections have been raised by the business community to this course, and, the report says, there seems to be a general recognition of the fact that, while prohibition from the enemy countries is effective during the war, it does not assist the equally important object of arranging for preferential reciprocal trading with the outlying parts of the Empire and Allied Countries.

The committee, therefore, have come to the conclusion that a tentative tariff for, say, five years on an ad valorem basis, might be applied almost immediately. Assuming the adoption of a tentative tariff, the committee suggest the appointment of a Royal Commission to consider the necessity or otherwise of altering the system of ad valorem duties to specific duties, and of increasing or modifying such duties.

### Triple Application Tariff

The committee go even further than this in their practical suggestions. After consulting representatives of the various interests concerned, they have formulated a scheme for a tentative tariff, which, we venture to hope, will be adopted in principle by the Government. It provides a three column tariff, giving "general," "maximum," and "minimum" rates of duties. The maximum rates are for enemy countries, the minimum rates for British Possessions and our present Allies, and the general for neutral countries.

Thus, on imports of wholly manufactured goods from British Possessions and our Allies, the minimum rate would be 10 per cent., the Dominions being entitled to a reduction equal to the preference they accord to the Mother Country. From neutral countries the rate would be 20 per cent., with a surtax equal to the preference given to other countries; and from enemy countries the rate of duty would be 30 per cent. Similarly, with regard to semi-manufactured goods for further use in manufacture, the proposed rate of duty on goods from within the Empire and from the Allies would be 6 per cent.;

on the goods from the neutral countries 10 per cent.; and on enemy goods 15 per cent. Raw foodstuffs would come in free from the Dominions and our Allies, while those from neutral countries would pay 2½ per cent., and from enemy countries 5 per cent. On manufactured foodstuffs the rates suggested are 2½, 5, and 7½ per cent. respectively.

It is not proposed to put any duty on raw materials, from whatever quarter they come, while the duties on wines, spirits, tobacco, and other articles now dutiable, might be maintained at their present rates during the period of the tentative tariff, plus 30 per cent. for imports from enemy countries. It is also suggested that special duties should be imposed on enemy shipping using the ports of the Allied Countries with preferential treatment for British Empire shipping.

The proposals made in this tentative tariff have been carefully thought out by a body of experienced business men, and are well worthy the consideration of the Government and of all who are interested in the commerce and industry of the country. The scheme does not profess to be a perfect one, but it will (1)-provide additional revenue, calculated at about 375 million dollars; (2)-establish Imperial preference; (3)-increase trade with our Allies; (4)-give a moderate amount of protection to British labour and capital; (5)-provide a means for future tariff negotiations with neutral countries; (6) penalise the trade and shipping of present enemy countries with the British Empire and Allied countries.

It is recognised by men of all parties that the attainment of these objects is necessary not only to our industrial and commercial prosperity, but to our very existence as a great Power, and it is clear to everyone that they cannot be secured except upon the basis of a scientific tariff framed on lines similar in principle to those above laid down.

## FORWARDING OF DOCUMENTS

BILLS of lading and consular invoices should be forwarded promptly to the consignee of the goods, so that they may be in his possession at the time of the arrival of the shipment, or even before, if possible. Should the consignee be without these documents when the goods arrive at their destination, they might have to be stored at his expense and risk, or he might be compelled at an inconvenience, to give a bond for the production of the papers. When consular invoices are not required, shippers should forward to the consignee itemized invoices, showing the quantities, brands, grades, prices, etc., of the different goods, for the purpose of entering same at the custom house abroad.

# Single Purpose vs. Automatic Multi-Cutting Machines

## "Automatic Manufacturer's Criticism"

*The subject matter of the accompanying article constitutes, as will be noted, the criticism of a contribution which appeared under the above title in a recent issue of the Automobile Engineer. In view of the development of single purpose machines for munitions manufacture in Canadian plants, a perusal of what follows should be found unusually interesting.*

**I**N a recent issue of the "Automobile Engineer," the writer of an article under the above heading, attempts to show the advantages of manufacturing by simple operations done on simple process machines, in preference to the more elaborate operations done on automatic turning machines. He takes as

turning machines, at costs with which no simple machine can compete, and as the tooling of automatic turning machines for shells which are made from pieces of bar material is very similar to the tooling of automatic screw machines, it rather weakens the case for simple lathes for our contemporary to rule automatic screw machines entirely out of the discussion.

### Initial and Installation Cost of Automatics

It is stated that the automatic turning machine is expensive, and the cost of installation high. This is certainly true, if the standard of comparison is the engine lathe, but the automatic turning machine is very little more expensive than a turret lathe of equal capacity. Since by the use of multi-cutting

chines, which perform the equivalent operations on the automatic.

The necessity for tools of special design and shape is also stated to be a disadvantage of the automatic turning machine. This may be assumed to include such tools as forming cutters, and it would be interesting to know how the simple lathe would handle any forming operation except with a tool of the same design as used on the automatic turning machine. The argument that special cams are required for each piece of work does not refer to the machines of our manufacture, which are fitted with our patent self-selecting feed motion, a feature which enables any tool to be used with the most suitable feed without changing the cams.

### Low Labor Cost of Automatics

The most important feature of the automatic turning machine is undoubtedly the extremely low labour cost of operation obtained by the fact that all the cutting tools are automatically operated, while the only manual work necessary, apart from tool setting, is for the pieces to be put in the chuck, and removed when finished. This enables one operator to attend to from three to six machines, depending upon the length of the operation. It is therefore, misleading to say that since "the low operation costs are dependent upon the number of machines installed,.....a considerable amount of money must be spent on automatic machinery before they can be operated on an economical basis." It is obvious that if only two machines

FIG. 1.

his example the methods which are extensively used on shell work, and his article suggests that the use of automatic turning machines for large quantities of repetition work, such as is met with in automobile practice, is not the paying proposition that the makers of such machines claim; also that the tendency of future workshop practice will be towards the use of simple lathes operated by unskilled labour.

### The Automatic Challenge

As makers of the latter, we—Alfred Herbert Ltd., Coventy, England have at least a first hand knowledge of our subject, and can hardly be expected to let such statements go by unchallenged. It has never been claimed that all work is suitable for automatic turning machines, and the analogy between shell manufacture and automobile manufacture is not a fair one, for a large amount of shell work is quite unsuitable for production by automatic turning machine methods, whereas on the larger shells the operations are long, and can be handled well on single operation machines. The smaller shells, which can be made from pieces cut-off from the bar, are, however, being regularly made on automatic

tools, the output of automatic turning machines it admittedly higher than that of an engine lathe, it follows that the number of engine lathes required for a given production will greatly exceed the number of automatic turning machines, and consequently the cost of automatic turning machines will compare favourably with the cost of engine lathes of equal productive capacity. Against the simple lathes are also the facts that they need more floor space, more operators, chucks, belting, power, lighting, and other contingencies, which, although not appearing in the first cost, all make the automatic turning machine the more profitable investment.

Another very important disadvantage in the simple lathe plant is that a very large volume of work must be put in hand at one time if all the lathes are to work simultaneously, as is suggested, and the inequality in the time for each operation must make it difficult to balance the output. We are told that the setting up of automatic turning machine tools is a lengthy operation, and consequently expensive. It will probably be found, however, that this setting up time is no more than the aggregate time for setting up the numerous simple ma-

FIG. 2.

were installed, it would still be an economical proposition, for the labor cost would be reduced directly one man operates more than one machine. The maximum saving would be obtained when from four to six machines were put

down, as any further extension of the battery calls for a proportionately greater number of operators.

#### Supervision Feature

The advocate of simple engine lathes tells us he "is given to understand" that the automatic turning machine can

most expensive part of the tool outfit of the automatic turning machine is the combination tool holders. These, however, are common to practically every piece of work which can be put on the machine, therefore, although the cost of the first set of tools may appear high,

ously, and it is suggested that distortion is caused by this. This again is entirely a question of correct tool designs. After the roughing cuts, it is not to be expected that the work is true, but the finishing cuts remove all this inaccuracy, and when correctly set, remove only a minimum amount. It would be extremely bad tool design to arrange an accurate finish turning cut at the same time as a rough grooving operation, and no one familiar with good tool practice would think of doing so.

It is also suggested that in order to stand the strain caused by the multi-cutting tools, the work must be of a robust nature, otherwise it will be distorted in chucking. This again is entirely a question of correct chucking, and the provision of suitable chucking pieces of clamping arrangements makes this objection disappear. An instance of a frail piece of work chucked on an automatic turning machine is shown in Fig. 1. This is an end shield of an electric motor, which has to be machined to very fine limits of accuracy. The driving is done from the central web by means of a plate fitted to the chuck. At this point, the work is stiff, and there is no possibility of distortion. The chuck jaws grip the work lightly round the rim, and only serve to centralize the work.

When a high degree of concentricity is required between the outside diameter and the bore, the fact that the outside diameter and the bore are machined at the same setting will ensure this, providing the boring bars are piloted in the chuck. At the second operation where the diameter has to be machined true with the previously finished hole, the required concentricity may be obtained by using a chucking arrangement as in Fig. 2. In this case, the work is gripped by the soft jaws of a Coventry chuck, and located central by a peg fitting in the bore. This peg extends into a bush carried in the combination tool, and ensures the work being turned true with the surfaces finished at the first operation. If this degree of accuracy

FIG. 3.

be operated by unskilled labor, and deduces from this that it is, therefore, necessary to give the operators a great deal of supervision. As in the opening part of his article, he states that the use of simple lathes was necessitated by the shortage of skilled labor at the outbreak of war, it is difficult to reconcile the two statements, especially as admittedly, the use of automatic turning machines reduces the number of operators necessary.

Skilled supervision in tool setting and gauging is equally as necessary on simple lathes as on the automatic turning machines, while the latter machines are the less likely to produce inaccurate work, as of course, the diameters and lengths produced by the cutting tools are all determined by stops. The argument is also advanced that castings or forgings to be used on automatic turning machines must be made to very fine limits at some additional cost, so as to make them as uniform in shape as possible. A shop manufacturing by modern methods, and turning out work in sufficient quantities to justify the installation of automatic turning machines, would of necessity be using machine moulded castings and drop forgings, the commercial accuracy of which is quite sufficient for the automatic turning machines, and therefore involves no additional expense on this account.

#### Tool Cost of Automatics

The high cost of tools, has always been stated to be one of the disadvantages of the automatic turning machines, but the fact is lost sight of by the simple lathe advocate, that many of the tools used on automatic turning machines are common to the hand operated turret lathes and engine lathes, so that many of these will already be in existence. The

extra tools necessary for each successive sample becomes less as the scope of the work increases, so that the greater the variety of work, the smaller is the proportionate tool cost. The argument that there is a large amount of capital locked up in the tool stores is therefore fallacious, when it is realized that the cost of the particular part of the tool equipment peculiar to each article is small.

#### Cutting Speed Bogey

The writer in the "Automobile Engineer" seems to be under the impression that it is necessary to use cutting speeds on an automatic turning machine much slower than those used on the simple lathe, in order to obtain a longer life of the cutting tools before regrinding. These precautionary slow cutting speeds are unnecessary if the tool layout is correctly designed. The cutters which do the bulk of the work, and need regrinding oftenest, are obviously the roughing cutters, the setting of which need not be accurate, and which consequently can be sharpened and replaced quickly when they give out.

It is very questionable whether slowing down the cutting speeds really does lengthen the life of the cutting tools; if measured in hours it certainly may appear to do so, but the output per grinding will be found to be much the same, whether the machine is run fast or slow, within reasonable limits. The idle or non-cutting motions of the automatic are carried out on a fixed fast feed, and on a piece of work taking 20 minutes to machine, only one minute is non-cutting time, a negligible proportion.

#### Work Distortion

On automatic turning machines several tools are often cutting simultane-

FIG. 4.

is still insufficient, the obvious way to finish is by grinding, and no one familiar with modern shop practice would suggest finish turning on a mandril in a lathe.

In selecting a concrete example for discussion in relation to the arguments

advanced for the simple lathe, the writer in the "Automobile Engineer" takes a piston, which is probably the kind of work on which the simple lathe would make the best show. The design selected is shown in Fig. 3, and it will be noted that the dome of this piston is a straight bevel, which has obviously been chosen so that the hypothetical piston can be faced by a straight cut from the compound rest. The sequence of operations suggested for machining this piston on the ordinary lathe has evidently been drawn up by some one unfamiliar with the best practice in this work, and in brief, is as follows:

1.—Bore and face open end of piston, holding by the outside diameter in a lathe chuck.

2.—Mount on face plate chuck, and rough and finish turn outside diameter.

3.—Rough and finish face end.

4.—Rough and finish groove for piston rings, and form clearance around gudgeon pin boss.

It will be seen from operation (1) that gripping by the outside in a chuck does not ensure the inside black surface running true, as the inside may be eccentric, and therefore the walls will not be of even thickness when the outside is turned. Neither will the dome of the piston be of uniform thickness, as no provision is made in operation (1) for facing the open end the correct distance from the inside end. It should also be noted that if the simple lathe process is carried out to its logical conclusion, operations (2), (3), and (4) will each have to be split up into two further operations each, namely, roughing and finishing, making seven operations in all.

#### Production Comparison—Automatic

Compare with this, our method of machining the same piston on an automatic turning machine, as shown in Figs. 3 and 4. At the first operation (Fig. 3), the piston is gripped from the inside by the special expanding arbor operated by rod and hand wheel. The turning is done from the turret with the combination tool, while to face the conical dome a very simple method is adopted. The strip which clamps the cross slide to the bed shears is removed and instead are fitted two tapered strips, one on each side of the shears. This has the effect of inclining the cross slide to the spindle at an angle determined by the taper on the strips, and angular facing thus becomes as easy a matter as straight facing.

It will be noticed that by the method above described the dome of each piston is turned to an equal thickness, as the inside of the dome is pushed to the same position on the arbor every time. This makes the subsequent operation of finishing the open end to a definite length an easy matter.

The turning and the rough grooving proceed simultaneously, and it will be noted that the tools, apart from the combination tool, are no more expensive or elaborate than would be used on the simple lathe. The combination tool is, of course, part of the standard equipment, and is not peculiar to this work any more than is the saddle of the ordinary lathe.

It is very important to notice that each simple lathe requires its own chucking arrangement, so that if these are considered as part of the tool equipment, as they certainly should be, the cost of the automatic turning machine tool outfit will compare very favorably with that of the simple lathes. The time of production for this operation on the automatic turning machine on a piston, say  $4\frac{1}{2}$  in. diameter,  $5\frac{5}{8}$  in. long, would

FIG. 5.

be  $8\frac{1}{2}$  minutes; allowing one minute for chucking, this makes a total of  $9\frac{1}{2}$  minutes. Doing the same operations on a simple lathe, using the same feeds and speeds, would take  $10\frac{1}{2}$  minutes; with three chuckings at one minute each, this makes a total of  $13\frac{1}{2}$  minutes.

By our method, the next operation is to bore and face the open end of the piston, holding it in soft jaws, and using an ordinary lathe. The fact that we recommend this type of machine for this operation shows that we are not so biassed as to advocate automatic turning machines for every operation. This operation is common to the simple lathe process (operation 1), and therefore need not affect the comparison.

The next operation is done on the automatic turning machine, and the piston is now drawn back by the gudgeon pin bosses on to a face plate fixture (Fig. 4), which spigots in the open end. It will be seen that this holds it entirely without distortion. A finishing cut is then taken over the outside, so as to leave sufficient for grinding. The grooves are finish formed, and the end of the piston faced, the tool layout being exactly the same as shown in Fig. 3, except that there is another tool used

to form the clearance around the gudgeon pin bosses. The machining time is seven minutes, and the chucking time one minute, which make a total of eight minutes. The equivalent operations done on the engine lathe at the same feeds and speeds would take ten minutes, and the chucking time three minutes, which makes a total of thirteen minutes.

#### Product Comparison—Labor Cost

We may now proceed to investigate the comparative labor cost of production by the two methods, and in doing this, we will base our figures upon actual labor costs, which have been furnished us by a firm using both automatic turning machines, and female labor on simpler machines. In this particular works, there are eleven automatic turning machines, which are run continuous-

ly day and night. The day shift consists of a skilled tool-setter, an improver who is also able to set up the smaller machines, an unskilled feeder, and a boy. The night shift consists of two unskilled feeders only, as the setting up is done entirely by the skilled man on the day shift. The average labor cost per machine per hour of this battery is at the present time 3.6 cents. On the simpler machines, where female and boy

labor is employed, the labor cost per machine per hour is 8 cents; all classes of operators on both types of machines are in addition making a bonus which averages 85 per cent.

On the piston under consideration, the total time of production on the automatic turning machine is  $17\frac{1}{2}$  minutes, which gives a labor cost, exclusive of setting up time and bonus, of 1.04 cents each. On the simpler lathes, the time of production is 26 $\frac{1}{2}$  minutes, which gives a labor cost of 3.5 cents each, exclusive of setting up time and bonus. It will thus be seen that the cost of production on simple lathes is between three and four times the cost of production on automatic turning machines, while on the other more involved work, such as front and rear wheel hubs, differential gear cases, differential boxes (Fig. 5), and gears, the automatic turning machine will show even greater savings.

#### Miscellaneous Comparisons

In the article in the "Automobile Engineer," the writer concludes by citing some instances of work which was produced on automatic turning machines, in which comparison is made with a time of production on simple lathes to

the advantage of the latter. We have investigated these times of production very carefully, and are safe in saying that they reveal the fact that the automatic turning machines were being improperly run, either from lack of correct tool equipment, or other causes.

An instance is given of a pulley, 10-in. diameter by 4-in. face, which was machined in 42 minutes; in the ordinary way, we would guarantee to machine this in 23 minutes. Another pulley was 12-in. diameter by 6½ in. face, and was machined in 61 minutes; the time of production for this should have been no longer than 40 minutes, if the machines were running properly. In another instance, a gear wheel 10-in. diameter by 1-in. face, was being machined in 18½ minutes; the time for this should not have exceeded 9½ minutes. The last instance was a 6-in. cone pinion, which was machined on the automatic turning machine in 63 minutes, whereas, the time should not have exceeded 27 minutes.

The times in which these articles should be produced on automatic turning machines according to our calculations, are such as we should be prepared to guarantee, and we do not think we shall be accused of boastfulness, when we say that "we fulfil our guarantees."

### CANADIAN PACIFIC OCEAN SERVICES

ALL the steamers of the Canadian Pacific Ocean Services are again in commission on their old route, and it is needless to say their return has been welcomed by travellers and shippers alike throughout the whole of the Far East. The resumption of this service has brought about certain changes in the personnel of the executive staff of the Company in China and Japan. The following list of changes has been furnished.

J. W. Wallace, appointed to general agent, Hong Kong Territory; Hong Kong, China, Straits Settlements, and India; relieving D. W. Craddock, who goes on leave of absence.

L. E. N. Ryan, of Samuel, Samuel & Co., Yokohama, appointed agent, Shanghai, relieving H. Thomas, acting agent, resigned.

A. J. Blaisdell, of St. Louis, appointed general agent, Passenger Department, Territory Shanghai and North China; new position.

T. G. Turnbull, appointed passenger agent, Shanghai.

P. D. Sutherland, appointed general agent, Passenger Department, Hong Kong new position.

J. R. Shaw, appointed passenger agent, Manila.

F. M. Flanagan, appointed passenger agent, Kobe.

### POST BELLUM GERMAN MARKETS

THE new directorate of the Manchester Chamber of Commerce decided to consolidate their position by asking for a decisive opinion of its members as to the trend of policy which would best secure the future of the well-being of the trade and industry of the British Empire. The Chamber in their resolution, which has now received the general sympathy of its members, considers it essential that after the war the same facilities for trade with the British Empire should not be allowed to our enemies as those granted to our Allies and to neutral nations, and particularly that steps should be taken, not only to render dumping impossible, but also to eliminate effectually enemy influences so active in operation prior to the war. The Chamber also urge that immediate consideration be given by the Government to the desirability of preferential reciprocal trading relations between all parts of the British Empire and as far as possible our Allies.

### CANADA'S EXPORT TRADE

CANADA'S export trade continues to expand, but it may be noted that her imports are also showing substantial monthly increases. For five months, January to May inclusive, total imports to this country amounted to \$283,605,680, against about \$170,000,000 for the corresponding period of last year. The following table shows exports by months from January to May, with the increases over the corresponding months of last year:

Month	Total	Increase.
January ....	\$ 85,559,782	\$54 729,445
February ....	58,879,321	26,227,332
March .....	89,772,422	20,089,603
April .....	55,372,720	19,115,445
May .....	106,000,000	61,023,623

Exports of agricultural products in May reached the high figure of \$47,433,750, as compared with \$12,746,727 a year ago. The movement abroad of manufactured goods is about 75 per cent. greater than last year, as the following indicates:

Month	Total	Increase.
January .....	\$47,015,283	\$39,246,137
February ....	28,606,680	19,624,041
March .....	47,013,766	31,412,986
April .....	21,573,078	8,351,420
May .....	27,734,477	11,613,328

### APPRECIATIONS OF SIR GEORGE FOSTER

LORD NORTHCLEFFE paid a neat compliment to Hon. Sir George Foster, Canada's Minister of Trade and Commerce, on June 24, at the Australian dinner in honor of Premier Hughes, of

Australia. In supporting the principal toast, Lord Northcliffe said he did not know why a plain man of affairs should be called upon when there were assembled at the table probably the five best orators of the British Empire namely Lord Rosebery; that most eloquent of all Canadians, Sir George E. Foster, Lord Grey, Col. Winston Churchill and Premier Hughes, of Australia.

Reynolds' Newspaper, in an open letter extending a welcome to Sir George Foster, credits the Canadian Minister of Trade and Commerce with a magnetic personality, great vision and high ideals, combined with practical experience as a man of affairs.

### GAS ENGINES FOR BLAST FURNACE GAS

IN a paper by Professor Hubert, Liege University, Belgium, before the Iron and Steel Institute, it is noted that the utilization of blast furnace gas in gas engines may be considered to date from 1894, when experiments were begun by B. H. Thwaite at the Glasgow (Scotland) Iron Works, and almost contemporaneously similar experiments were independently made at Seraing, Belgium, and at Hoerde, Germany. In 1897 the Cockerill Co., at Seraing, after experimenting on an 8-h.p. engine, built the first large blast-furnace gas engine, developing 200 h.p. This engine, put into operation in April, 1898, consumed 3,329 cu. m. of gas per horsepower hour. The calorific power of the gas was 981 calories per cubic meter. From this point rapid progress was made, until at present engines of 8000 h.p. in 4-cylinder types, and of 3200 h.p. in 2-cylinder types have been built by the Cockerill Co.

#### The Cockerill Product

The latest type of engine built by them has had unusual precautions taken with it to avoid the accidents common to all large gas engines, such as fractures of the cylinder heads, pistons, piston rods, connecting rods, and the bending or breakage of crank-shafts. Higher average working pressures are obtained by the use of a built-up piston, bolted to a ring forged on a rod. The mass of metal presented to the gas flame is reduced, thereby avoiding the danger of pre-ignition or premature explosion. Pressures of 78 lbs. per sq. in., instead of the usual 64 lbs. can be allowed, thereby securing higher compression and insuring high thermal efficiency and a limited gas consumption.

The governing mechanism allows a speed variation of plus or minus 2 per cent. for driving dynamos, while a hand mechanism permits of this being varied, while running, from 10 to 15 per cent.

The conditions of wide speed variation required by blowing engines have been met by a new system of governing which permits the mean speed of the engine to be adjusted as desired to 49, 90, 126 and 262 r.p.m. and to be further varied by governing within 50, 24, 16 and 11 per cent. respectively of the mean speeds.

#### Other Successful Products

Of successful gas engines of other types probably the most interesting are the high-speed vertical, multi-cylinder engines built by the British Westinghouse Co., and the National Gas Engine Co. These consist of units compounded together, each comprising two vertical single-acting four-cycle cylinders, the pistons of which are mounted on the same rod. Each unit drives a crank on the engine shaft and develops, usually, 250 h.p. Increased power is obtained by increasing the number of units. The engines run at from 200 to 250 r.p.m., which permits of their use for driving turboblowers. The weight per horsepower of these engines is only about one-half that of horizontal, double-acting, two-cylinder tandem engines.

#### Blast Furnace Gas Utilization

The latest development in the economic utilization of blast-furnace gas consists in passing the exhaust gases from the gas engine through a boiler and economizer, wherein steam is generated at a pressure of about 114 lbs. per square inch. The amount of heat carried off in the exhaust from the engines may be as high as 2600 B.t.u. per horsepower hour. In the arrangement adopted at the Cockerill Works, the gas enters the boiler at about 450 degs. Fah., and is reduced in the economizer to 230 degs. The gases from four gas engines aggregating 5000 b. h.p. are now employed in this manner.

About 1.93 lbs. of steam per electrical horsepower of the engine are generated by this means, developing about 650 h.p. in a steam turbine. The boilers recover about 55 per cent. of the heat of the gases and increase the thermal efficiency of the engine about 13 per cent. With an installation of four blast-furnace gas engines, developing 10,000 h.p. and costing \$380,000, the cost of the recovery appliances (boilers and turbine) is put at \$46,000. With interest and redemption of capital taken at 13 per cent., and with an annual outlay of \$2,000 for wages and maintenance, the saving to be effected by the recovery of the heat in the exhaust will amount to approximately \$19,400 per year.

#### BOOTS FOR RUSSIAN ARMY

A SPECIAL article in a recent issue of the Yorkshire Post gives some interest-

ing information with regard to the millions of boots which British manufacturers are turning out for the Russian Army. In the course of his remarks the writer says: The British Army Contract Department are now making rapid progress with the details regarding the 9,000,000 pairs of boots of several types which are required from British boot and shoe manufacturers to meet the needs of the Russian Army.

This order is by far the largest ever undertaken in Britain, and the magnitude of the task will be grasped when it is stated that 3,000,000 were required for delivery before the end of June. To assemble the various kinds of leather required to produce on an average more than 55,000 pairs of boots per day so as to keep to the time stipulated, involves very great skill and complete organization, in order that all the machinery may be kept working up to its full capacity. The boots are of weights and sizes for giants, and the Russian troops for whom they are intended must be men of magnificent physique. The sizes run from 10's to 15's, and 7 lb. to 8 lb. per pair are quite common weights. With boots of this special character, and of such exceptional sizes and designs, there were enormous preliminary arrangements to make before the machines could get into active operation. Thousands of metal lasts had to be cast, as each boot had to be lasted whilst the various operations were being carried through by the machines, and, of course, different metal lasts have to be used for every size or half-size manufactured.

Then, again, thousands of massive cutting dies of steel (called knives in the trade) had to be manufactured in order to stamp out in a machine the various sizes of soles and upper parts, and also for the heel builders, and distributed in sufficient numbers to every factory where the boots were being manufactured. Duplicate sets were also required for the purpose of the cutting edges being ground and sharpened by the boot and shoe engineers. It will be seen that this was a gigantic undertaking, especially when it is remembered that all this is in addition to providing for the ordinary requirements of the general home and Colonial trade for all classes of footwear, and also in addition to meeting the constant needs of the British Navy and the ever-expanding British Army. The great task was only rendered possible by the great revolution in automatic or semi-automatic boot and shoe machinery. By this means production has grown by leaps and bounds in extent, and the character and artistic appearance, especially of ladies' shoes, has been greatly enhanced. A shortage of footwear for general purposes is fear-

ed, and intense activity will prevail in the boot industry for many months.

#### “LEGAL,” “NET” AND “GROSS” WEIGHTS

IN arranging consular documents for some countries, it is necessary to state the “net” as well as the “gross” weight. The “net” weight represents the weight of the merchandise in its original package. The “gross” weight is the entire weight of the package as shipped. The New York Journal of Commerce gives the following definitions of net, gross, and legal weight:—

Strictly speaking the net weight of goods is simply the weight of the goods themselves, without any package or container of any kind. The gross weight is the weight of the goods and the package containing them. “Legal” weight is determined in such manner as the particular law in question may direct, and there is no other way to find it except by consulting the law. While net weight is, strictly, such as we have defined it to be, some tariff laws give it a special definition for the purpose of assessing and collecting duties. This is true also of “legal weight,” and it is sometimes true even of gross weight, thus actual weight of the goods freed from all packing, receptacles, or wrappers.” In other cases dutiable net weight does not include the weight of any common exterior cover, receptacle, package, wrappers or packing, but includes all interior or immediate receptacles. The Mexican definition of “legal weight” is more or less common and is as follows:—

By legal weight is meant the weight of the goods, together with that of their interior packing, such as wrappers, receptacles, card board and wooden boxes, tins, etc., inclosed in the outer packing case in which imported. When goods dutiable on legal weight are not inclosed in interior packages, but in one outside inclosure only, the intrinsic weight of such goods will be considered as legal weight. The important point is to note that the law of the particular country in question must be consulted as to the definition of these terms in the tariff act of that country.

**Munition Board Orders Cars.** — The first order placed for the Russian Government through the Imperial Munitions Board, is for 7,000 box cars, and has been divided chiefly between the Canadian Car and Foundry Co., and the National Steel Car Co. The total is likely to reach 50,000, and orders for locomotives and other railway equipment, except rails, will follow. Manufacturers are being urged to give these preference to munitions orders, as railway equipment is badly needed.

# PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

## LARGE SHELL WEIGHING SCALE

**O**WING to the peculiar nature of the materials and the extreme accuracy required, ordinary weigh scales were found to be not entirely suited to the successful and economic weighing of the shell. The high and low limits in many instances were very close, and the slightest error in registration would often cause considerable inconvenience at the termination of operations. Many scales have been specially designed and constructed for the purpose.

The accompanying illustration shows a shell weighing scale recently designed by the Canadian Fairbanks-Morse Co., of Montreal, its capacity ranging from 6 in. to 12 in. shell diameters. The scale is supported upon a specially constructed framework, erected above a long bench upon which the shells are placed and then rolled on to a special platform that hangs by four rods from the cross beam of the scale. The construction is of the simplest form, the whole mechanism being well balanced, accurate and reliable, besides requiring little adjustment or attention. A relieving device is fitted, and the register guarantee is within  $\frac{1}{8}$  ounce of the absolute weight. The scale can be furnished either for use when shells are rolled on, or with a different type of platform when the

shells are set on end. A plus and minus beam shows at a glance just how much the shell weight is over or under the required amount.

## TUBE SCRAPER

THE tube scraper illustrated, and known as type K.C., is a product of the Babcock & Wilcox Co., Toronto, Montreal and London, England, and forms an accessory to their well known water-

At the same time, move the scraper up and down the tube, slightly twisting the handle while doing so, until the apparatus comes out at the bottom of the tube. Twice down is claimed to be sufficient to thoroughly clean the tube.

## IMPROVED BAR CUTTING-OFF MACHINE

THE Southwark Foundry & Machine Co., Philadelphia, Pa., are marketing a

TUBE SCRAPER FOR B. & W. WATER TUBE BOILERS

tube boilers. A special claim made for this scraper is its efficiency in dealing with hard scale. The scraper is attached to a length of wrought iron tubing screwed  $\frac{3}{4}$  in. gas thread, which in turn is connected to a water supply by means of a rubber hose for conveying a small stream of water through the centre of the tool, in order to cool the cutters and wash away the scale removed. A small tap is fixed between the wrought iron tubing and the hose for regulating the water supply. The cutting edges of the rollers are of a radius to suit the size of tube, being contained within a circle the same diameter as the inside diameter of the latter. It will be seen, therefore, that, when all scale has been removed, the rollers will not cut into the surface of tube. To operate, remove the hand-hole caps, insert the scraper, turn on the tap at the top end of handle, and allow the water to flow.

new size and type of air-operated cutting-off machine for projectile bar stock, the latter embracing from 7 in. to 10 in. diameters. There is also introduced in its construction a special arrangement for feeding the tools into the stock, and the incorporation of guide cylinders to handle bars that may not be absolutely round.

A heavy cast iron bed supports at one end a quick-acting chuck for gripping

IMPROVED BAR CUTTING-OFF MACHINE.

the bar, also the gearing to transmit power from the driving motor for rotating the stock. A number of cutting-off heads are mounted on the bed and consist of steel castings with five air cylind-

LARGE SHELL-WEIGHING SCALE

ers on each. Three of the cylinders operate the cutting-off tools. Air is admitted at the top of the cylinder and divides into three parts to operate the three tools, the one pointing downward being acted upon directly, while those at the sides are operated through a system of links. The lower tools operate horizontally, and all three tools cut in the same skarf.

The remaining cylinders operate guides which centre the bar in the ma-

six minutes. The illustration is a part sectional elevation of the machine and shows the arrangement for admitting air to the horizontal pistons.

### RAPID PRODUCTION PUNCH PRESS

A NEW rotary punch press, in which the punch and the die drums are mounted on independent shafts, has been designed by the Malm Machine Co., Day-

RAPID PRODUCTION PUNCH PRESS.

chine, this arrangement making possible the cutting of bars that are out of round to the extent of  $\frac{1}{2}$  in. in 12 ft. The use of compressed air to bring the tools in contact with the work enables the former to accommodate themselves to irregularities in the bar and in some cases bars that are chipped badly have been handled. The piping used to convey the air to the different heads is arranged in multiple, each head drawing its supply directly from the air supply line. All the gears are mounted between bearings and the pinions do not overhang. A flexible coupling is located between the motor and the pinion, the latter being journaled in ring oiling bearings, while a substantial cast iron base is located underneath the motor and pinion bearings.

Air cylinders and a small roller table, which is placed in line with the end of the machine, are employed to handle the stock. This air cylinder pushes the bar through the bushings on the cutting-off head into the chuck, and, when the cut in the bar has reached the predetermined depth, the machine is stopped and the air cylinder at the chuck end pushes the bar from the machine on the roller table from which it goes to the breaking equipment. As the bars are handled in full, even after being cut, it is pointed out that the handling is rapid.

The cutting time in seconds is approximately three and one-half times the square of the diameter in inches, the usual practice being to leave about 15 per cent. of the original area uncut for the fracture test required by the specifications of the various governments covering the production of shell blanks. For example, a round bar 10 in. in diameter will be cut from the outside to a point where it may be easily broken in about 350 seconds or a trifle less than

ton, Ohio. The punch drum is keyed on the punch driving shaft, while the die drum is mounted on an idler shaft, thus allowing it to revolve freely. Upon the punch drum are mounted multiple punches that engage a similar number of dies mounted on the die drum.

The material is fed from the rear of the machine by automatic feed rollers, and the punchings drop through the die slot into a chute and from there down to containers placed at the front of the machine. The machine is constructed with either one, two, or three heads, for either plain blanking or piercing, blank-

MECHANICAL TRIP HAMMER.

ing or piercing, blanking and forming. The punch shaft makes 50 r.p.m., and if the size of the part to be punched warrants putting 20 punches on the punch drum and the corresponding number of dies on the die drum, a machine thus equipped will turn out 1,000 complete pieces per minute. It is estimated that a 162 h.p. drive for the punch shaft is sufficient for the heaviest work.

The shape of the piece to be punched is immaterial, the thickness of stock can vary from 0.003 in. up to  $\frac{1}{8}$  in., while a width of 12 in. can readily be handled. This applies to the stock machines, but wider machines can be built. If the material is very thin and comes in spools, provision is made in the form of a winder designed to take care of the spool, but if the material is in sheets or strips, this is placed upon idlers and automatically fed by the feed rollers through the machine.

In addition to punching metal, the machine is claimed to be equally good on fiber or other goods, the speed in punching some classes of material, it is understood, being considerably faster than on a vertical punch press. For making washers up to  $\frac{1}{8}$  in. thick, an output of nearly ten times the record of vertical punch presses is said to be possible. It is emphasized also that with the rotary principle applied in this machine, a shearing cut is always made even should the punch or die get dull.

### MECHANICAL TRIP HAMMER

THE accompanying illustration shows a very interesting and highly efficient type of trip hammer, for the economic production of small forgings and other blacksmith or machine work. These hammers are made in a variety of sizes, to meet a diversity of needs. The mechanism is so constructed that the motion is conveyed to the head by means of parallel arms, so that the head is always held in a vertical position, and is so designed to allow any reasonable height of tool or thickness of metal to be worked. In some of these hammers provision is made for a lateral traverse of the head, by means of a fine pitch, rapid lead screw, operated through bevel gearing at one end of the machine; as a result swaging, punching, flattening or any similar work may be accomplished.

The hammer is operated by the depression of the treadle around the anvil. The arrangement of the springs is so designed that no accident can possibly occur through breakage.

In the heavier types of these hammers, the mechanical features of design are similar, with the exception of the lateral traverse of the head. Where two or more separate operations are required on the one piece, as die or swage work, multiple headed hammers are provided, which possess every means for the exact adjustment of die blocks or swages, and may also be

equipped to successfully operate on any desired shape of work.

The striking force of the hammer can be controlled by the variation in the depression of the foot treadle, which is directly connected to a block in a slotted link, one end of which is fulcrumed and the other secured to the lower end of the connecting rod. This rod is held in a neutral position by means of heavy springs, one on either side of the crank, so that the action of the hammer is not a dead blow on the material, and consequently does not chill the work in operation. These machines are intended to operate at an average speed of 130 blows a minute, with a striking force of from 3 to 9 cwt. according to the size of the machine; but so economically is it produced that it takes less than one h.p. when working at its maximum. One of the chief features in connection with this hammer is the elimination of the helper, as one man can operate the hammer at the same time as he handles the work and to much better advantage.

The weight ranges from about 500 lbs. for the smallest size, to over 1800 lbs. for the largest size of single headed hammer; while the multiple headed types vary according to the number of heads and work requirements. These mechanical operated trip hammers are manufactured under the Blacker's Patent, and are being placed on the Canadian market by Alexander Gibb, St. Nicholas Bldg., Montreal.

### MARKETING B.C. LUMBER

THE British Columbia Government is actively engaged in investigating new markets for the lumber produced from her immense forests. The stand of merchantable timber in British Columbia, is estimated to reach the enormous total of four hundred billion feet (400,000,000,000) board measure, which is over half the total of all Canada. The annual cut is at present, in the neighborhood of only one and a half billion feet (1,500,000,000), board measure. The forests can, therefore, supply indefinitely a yield considerably greater than that.

British Columbia's location and export facilities demand that every effort be made to secure a full share of the export lumber trade, but the main markets for British Columbia forest products are on this continent. In proportion to population, Canada uses more lumber than any other country. Eastern Canada constitutes a natural field for the expansion of British Columbia's lumber markets, particularly now that the Panama Canal renders direct water shipment possible. The forest areas of Eastern Canada are already unable to supply the local demand. This is clearly shown in the official returns of imports.

### MARKET FOR CANADIAN LUMBER IN CUBA

THE following article, forwarded to the Department of Trade and Commerce, by J. C. Manzer, special representative of the New Brunswick Government in Havana, will be of interest to Canadians, showing as it does the wide market in Cuba for lumber, and the part that this island is taking in the industrial activity of the world.

Cuba imports annually about 600,000,000 feet of lumber. This consists, for the most part of pine, spruce and fir, and is imported in the form of inch boards, running from six inches to twelve inches in width; planks two or three inches thick and of various widths and deals sawn to various dimensions to conform with orders received. It is shipped just as it comes from the saw without being planed, and when imported in this form is not subject to duty. The greater part of this lumber comes from the United States, principally from the gulf of Mexico ports, but Canada supplies a large quantity which might be increased to a great extent.

A large part of this lumber is brought on schooners, but since the ferry service between Cuba and Key West has been in operation, considerable lumber from Florida and Georgia is shipped by rail. This lumber on arrival in Cuba is taken direct from the docks to the mills, where it is planed and made ready for building purposes. It is then shipped to all parts of the island. The increasing prosperity of the island has largely increased the demand for lumber of all kinds, but lack of vessels has prevented the necessary supply from being obtained, and consequently has curtailed building operations to a great extent.

The labourers in the cane fields, now that they are getting more pay for their work are no longer content to live in houses constructed of palm leaves, but are constructing wooden houses which are much more comfortable. The clerks in the business houses, many of whom have been living in small poorly ventilated rooms in the crowded parts of Havana, are now getting building lots outside the city where they are constructing houses, mostly of wood, where their families can enjoy the fresh air and sunshine. The business men are also building residences in the suburbs, mostly of brick or concrete, but even these require large quantities of lumber for doors, windows, staging, moulds for concrete, etc.

Spruce and pine from New Brunswick, Nova Scotia and Quebec; also spruce, fir, hemlock and cedar from British Columbia would be suitable for all building purposes in Cuba. Besides this class of lumber, Cuba imports quantities of

shingles, thousands of crates for fruit, shooks for packing cases, stave heads and hoops for making barrels, and large quantities of broom-handles. Canadian pine, spruce and fir would be quite suitable for the manufacture of fruit crates and packing cases. These are imported cut in exact lengths ready to be nailed together, and tied in bundles. Birch, maple and ash would be quite suitable for barrel heads, staves and hoops. These arrive tied in bundles, and when put together are used for packing beer. Canadian yellow birch and maple make the best broom-handles.

Canadian lumber will fill nearly all the requirements of the building trade in Cuba; and as Canada is a large seller of lumber while Cuba is a heavy buyer, it would be advisable as soon as the war is over, and conditions become normal again to make an effort to secure a larger proportion of this Cuban lumber trade.

### DOMINION REVENUES INCREASE

THE consolidated revenue of Canada for the three months of the fiscal year ending June 30, was \$50,772,903.92, and the expenditure was \$37,055,289. The revenue from all sources amounted to \$56,000,000. Of the expenditure only \$10,528,045 comes under consolidated fund account while \$26,527,243 is under capital, \$22,173,031 of which is war outlay. In the month of June last the war expenditure was \$12,439,187.93. During the three months' period the expenditure on both capital and revenue accounts outside of the capital outlay on war has decreased substantially, due to the policy of rigid economy adhered to by the spending departments of the Government. The June revenue increased from \$11,433,970 to \$17,600,149, the increase being found in nearly all branches including \$4,000,000 in customs.

The buoyancy of the Dominion's financial situation is shown throughout the statement. The total assets of the Dominion on June 30 were \$420,395,783, as against \$257,943,948 a year ago. The net debt increased from \$450,287,721 to \$593,910,637. The credit that Canada has extended to the British Government now totals \$150,000,000, and munition orders to this amount have been placed with her by the Imperial Government.

Canadian deposits on savings account total over \$700,000,000, having increased a little over \$100,000,000 during the 20 months of the war.

The Storey Pump & Equipment Co., Toronto, have recently installed two Morris turbine pumps, capacity 1,500,000 gallons each, for water supply at Camp Borden.

### HAS THE TRANSITION PERIOD BEGUN?

THE lessening demand in Canada and the United States for the smaller size shells is exhibited in the growing tendency to place on the market more or less complete equipments of machine tools and other appliances which have in past months done duty in production of these munitions. While nothing in the nature of a slump in small shell orders is immediately imminent, it is abundantly evident that requirements are being met in large measure within easy range of the various battle fronts. The gradual tapering off, noticeable both in number and quantity contracts for small shells might aptly be termed a "humane" proceeding, enabling as it does a reasonable opportunity for plant readjustment to either the production of the larger type shells or to such a condition as will facilitate return to the spheres of manufacture vacated in the early wartime urgency.

Here and there we find equipments offering, yet so far as we have been able to gather, their disposal has neither wrought hardships on the seller nor on the machine tool market as a whole. It may almost be said that the transition stage from wartime to peacetime production is already inaugurated. Judging from appearances, and having regard to the well-authenticated advices that something approaching another two-year period of active hostilities is being provided for, we are inclined to the opinion that the transition progress is now being steadily and systematically developed and that business disturbance will as a result be free from a succession of more or less intensive outbursts.

The demand for large shells may be said to show little abatement, and, to their manufacture, numerous Canadian plants formerly engaged on shrapnel, etc., are now turning their attention. Purchases of a heavier type of machine tools for that purpose continue to be satisfactory. It is not anticipated, however, that requirements will in any respect approach those of the shrapnel era. Whether significant or otherwise, it is worth noting that the additional financing in Canada on behalf of the Imperial Munitions Board, is, according to report at least, of quite modest proportions compared with that immediately preceding. Naturally, therefore, one would infer that a curtailed munitions output in Canada is in the immediate future highly probable. In any case, the manufacture of munitions and the aspect of the war as its result, have reached a stage at which our metal-working plants may not become too deeply or at least unwisely involved. Such a condition

as the latter would materially unsteady the transition movement in its meantime satisfactory progress.

### CANADIAN NICKEL AND THE "DEUTSCHLAND"

THE arrival of a German merchant submarine in an American Atlantic port has re-opened the controversy as to the export of nickel of Canadian origin. Nero fiddled while Rome burned, at least so we are told, and as if one such horrible example weren't enough even in nineteen hundred odd years of the same Christian era, we are asked to sit up and take notice of this latest and equally stupid performance. Digressing just a little more, and perhaps not so, it looks as if German vanity was badly punctured by a recent submarine ocean voyage achievement in which Canada figured to an appreciable extent.

What the Deutschland brought to the United States, and what she or her sisters may be permitted to take back from there, cut very little figure in this day of achievement and enterprise. It was only natural to expect, however, that Canada's little accomplishment in the direction already indicated would be subject for attack and that, if possible where the thrust would be most keenly felt. It was deemed only necessary to advertise the fact that nickel would constitute the major portion of the Deutschland's return voyage cargo, in order to strike us hard. It was well-known in Germany that we were not lacking in advocates of Canadian nickel being refined as well as mined within our borders, and that our nickel resources are easily the greatest in the world. Whether then the Deutschland takes back a cargo of refined nickel of Canadian origin or otherwise, the exploit has succeeded in opening the controversy concerning our nickel export.

On the subject of Canadian nickel export, we have had the most specific public assurances from British as well as Canadian Government officers, and the general disposition has been to accept such statements; their effect being that no nickel of Canadian territorial extraction does reach our meantime enemies. On the other hand, we have just as explicit assurances that our nickel is reaching the enemy, and while the leaning as to conviction may be altogether to the first named, nevertheless a horrible nightmare of uncertainty supervenes. Aside entirely from the holdful of nickel whose origin is open to question that the Deutschland will essay to land in Germany, isn't it rather a reflection on our public life that any question should arise as to the destination of Canadian mined nickel.

As we see it, the ultimate destination is somewhat hard to determine, particularly as the refining is done in a foreign country. On the other hand, were refining as well as mining purely Canadian, would we be able to control the ultimate destination? Not unless the entire sales were direct to Great Britain or her Allies. Without a doubt, Canadian nickel caters to the needs of the American domestic market, and may do more, in any case the purchase ramifications may reach as far as the hold of the Deutschland. It seems to us that unless the refined product of our nickel mines becomes a meantime monopoly purchase of Great Britain and her Allies, the openings to our enemy are many.

On the nickel refining and export questions, as on a myriad others that are ripe for action and settlement in this Dominion of Canada to-day, we have too much politics, too many politicians, and too few, if any statesmen. Until politics and politicians are displaced by statesmanship and statesmen, neither the nickel refining and export questions, nor the thousand and one other equally pressing problems, the solution of which halts Canada's progress, can be approached for settlement.

## INDUSTRIAL NOTABILITIES

**W**ILLIAM INGLIS, president, The John Inglis Co., manufacturers of boilers, engines, machinery, etc., Strachan Avenue, Toronto; Member of Commission to Investigate Labor Conditions in Munitions Factories, was born in Guelph, Ont., October 20, 1867, the son of the late John and Margaret (Lewis) Inglis.

WILLIAM INGLIS

He was educated at Guelph Public and High Schools, and became apprenticed to Inglis & Hunter, Guelph, Ontario, 1880. The factory was removed to Toronto in 1881, where he continued his work and learned the business thoroughly. In 1890 his father took him into partnership and the firm name became John Inglis & Sons. After the death of his father, in 1899, the business was continued under the same name until 1903, when the present company was incorporated, Mr. Inglis becoming president.

He is a member, Toronto Board of Trade; member, Canadian Manufacturers' Association, and chairman of its Engine and Boiler Section.

Mr. Inglis married Louise Hewett, daughter of William Hewett, Toronto, December 19, 1899, there being one daughter of the union.

His clubs are Toronto; Engineers (Toronto); R.C.Y.C.; Lakeview Golf and Country; O.J.C.; Parkdale Curling; Parkdale Bowling; and recreations: motoring, curling, bowling. His residence is 1286 King Street West, Toronto.

the first of September buying will again develop, consumers then interesting themselves in last quarter and next year's requirements. Agricultural implement makers are contracting for large tonnage of steel bars, and it is anticipated that additional orders for larger quantities will shortly be placed. It is impossible to satisfy the demand of plate consumers; as a result, deliveries are constantly getting in arrears. The mills are so rushed that delivery cannot be had for at least four or six months. Some producers can offer fairly early positions for small lots, but at premium prices. Blue annealed sheets are becoming easier, owing to the situation being relieved by the continued heavy production of some of the mills which have made better progress than expected. This has also been assisted by the policy of some mills not to take on heavy forward business. The Philadelphia quotation on blue annealed sheets has declined \$5 a ton. Domestic demand for tin plate is heavy, several large lots being required for last quarter delivery. Wire and wire products are in good demand, having increased during the past two weeks. One mill on the other side has advanced their prices \$4 a ton. Galvanized products have not yet been affected by the low level of spelter. Boiler tube demand is very heavy, and mills are booked ahead for many months.

**Metals**

The general condition of the metal market is unchanged. Copper is showing signs of becoming weaker, and prices are easier. Tin is quiet and weak. Spelter shows signs of returning strength, but nothing to indicate a continued rise. Lead is quiet, but comparatively firm, while antimony is becoming steadier.

**Copper.**—Very little has transpired in the copper situation. The general market is quiet and inactive. The consumption of copper at the present time is undoubtedly as great as ever, but users are not in the market for further supply, the stock on hand being sufficient for immediate needs. Future demand is very light. Producers are well supplied with orders, but unless additional war contracts are placed the possibilities are for a declining market, as domestic business is not sufficient to sustain the present high prices. No heavy sales are being made, and quotations are nominal, being based on resale offerings. While the London market is comparatively quiet, spot prices showing no change, the quotation on futures has advanced 10 shillings. Electro spot has declined £4 10s.; present quotations being £91 for standard spot; £89 10s. for futures, and £124 10s. for spot electro. The New York market is weaker, electrolytic having declined ¾c and castings ½c. Nominal quotations are 26½ cents for

## The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

**Montreal, Que., July 17, 1916.**—The industrial situation generally is still very encouraging. Much manufacturing activity is to be noted throughout the country. In addition to the volume of business being done in munitions, the domestic activity is constantly improving. A pleasing feature of the situation is shown in the statement recently issued by the Government, pointing out that during the past three months public expenditures have decreased considerably, and revenue has increased; the total revenue for the period being approximately 56 million dollars. The increase for June was \$6,000,000. The total assets of the Dominion have increased 62 per cent., while the total debt has only in-

creased about 32 per cent. In every direction prosperity is being demonstrated. Satisfactory crop conditions also continue to be reported.

**Pig Iron**

With the market quiet and inactive, there is little to report. Furnaces are very busy. Slight price movements are noted in foreign markets, but dealers here report unchanged conditions.

**Steel**

It is generally expected that, owing to the midsummer season, the production of steel of all descriptions will be materially reduced, but this will be offset by the comparative decline in placed orders. It is thought, however, that about

lake, 25½ cents for electrolytic, and 23½ cents for castings. Local dealers report a quiet market, with prices easier, there being a decline of ½ cent on lake and electrolytic and 1 cent on castings. This week's quotations are 31 cents for lake and electro, and 30 cents for castings.

**Tin.**—Dullness prevails, and the market continues very quiet. Little business is being done; consumers are apparently well covered for present requirements, and are awaiting the trend of general conditions. Concessions on quoted prices are no inducement to buyers, who are holding off from purchasing futures. London reports a weak market, with lower quotations, a general decline of £4 being noted. Latest cables show the market to stand at £169 for standard spot; futures 15 shillings stronger, with Straits tin at £170. New York has declined ¾c, the present nominal quotation being 38½ cents per pound. The local situation is unchanged with an undertone of weakness. Dealers are quoting 44 cents, a decline of 1 cent per pound.

**Spelter.**—While there is little to indicate that the market is again on the upward movement, the general situation is apparently stronger, and prices are steadier. Owing to the heavy production of spelter at the present time it is not considered likely that any great advance will be made, although prices may be firmer for a time. The decline was arrested by recent inquiry for fairly large quantities of metal and some good sales. The relative low price of spelter is creating some interest among galvanizers, and inquiries are general. The London market has taken on strength, an advance of £3 being shown on spot, and £2 10s. on futures; present quotations being £47 and £43 10s. respectively. New York prices are slightly easier, but the market is a little steadier; a decline of ½c on the week shows the current quotation to be 8.8 cents per pound. Local dealers are quoting 14 cents on a quiet market; this is a decline of 1 cent.

**Lead.**—The lead situation is practically unchanged. Due to the lower price which the outside interests have been offering, it is generally conceded that much business has been lost to the leading producers, with the result that the Trust has recently reduced its quotation. The effect has been to cause a further cut in the prices asked by independents. This metal is more active than any other, but comparatively quiet to what it has been. London is a little stronger, and American prices are from \$1 to \$2 a ton lower. The situation here is unchanged, dealers still asking 9 cents per pound.

**Antimony.**—The stagnant condition of antimony continues. Rumors of further munitions orders had an encouraging

effect upon the market, which has shown a steadier tone than for some time past. The American market, however, has declined another 1½ cents, and the quotation is now 14½ cents per pound. Dealers here report a further decline of 1 cent, the current price being 22 cents per pound.

**Aluminum.**—The market is unchanged with prices firm at 65 cents per pound.

#### Machine Tools and Supplies

The machine tool situation is unchanged. The demand for shell-making machinery is gradually becoming lighter, especially for the smaller equipments. Inquiries are still in the market for the heavier machines, many of which are still needed. The completion of early shell orders and the unlikelihood of additional large orders is gradually having the effect of bringing resale machinery on the market; but this consists largely of tools that have been used for the making of the smaller sizes of high explosive and shrapnel shells. The demand to meet domestic requirements continues

#### CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion \$100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

fairly good, and the volume of business along these lines is very encouraging. All kinds of supplies are still in great demand, deliveries being now much better.

#### Scrap

The market in old materials continues to fluctuate, and prices are subject to change from day to day. New York quotations generally show a decline over last week. Heavy brass is stronger, as is light copper, but crucible shows a decline. Quotations on nearly all metal scrap have declined from ¼ cent to 1½ cents per pound. Aluminum scrap is easier, new scrap having declined 2 cents per pound. Dealers here report an unchanged situation, with prices holding firm, but with a tendency to weaken.

**Toronto, Ont., July 18.**—The general situation in manufacturing circles continues favorable, considerable development taking place in many industries. Numerous factories are being extended to take care of the increased volume of business and from a financial standpoint a large number of concerns are in a

stronger position than they ever have been. Orders for munitions which are being distributed from time to time, principally for the larger calibre shells, promise to keep plants busy for the remainder of the year and well into 1917. The placing of orders for cars by the Imperial Munitions Board is a new development and indicates an extension of the Board's activities which will have a distinctly beneficial effect on certain industries in Canada.

#### Steel

The steel market is seasonably quiet but prices are firm, being sustained by the export business which continues heavy. Domestic business is lighter and there is less tendency to hold out for higher prices, which is a further indication that the upward movement has stopped. The demand for shell forgings is as urgent as ever, so much so, that enquiries have been sent to the States for this material for delivery during the second quarter of 1917. The Canadian mills are so busy on shell material that the rolling of rails has to be neglected and orders for the latter being placed in the States by Canadian railways. There are no price changes of importance to note and the situation with regard to wrought iron pipe, boiler tubes, boiler plates, etc., is also unchanged.

The situation in the galvanized sheet market is steadily improving following the consistent decline in spelter. Prices of galvanized sheets have declined slightly but not in proportion to the drop in spelter, as manufacturers are still receiving higher priced spelter on older contracts and will not begin to get deliveries at present prices for some weeks yet. Furthermore, other raw materials such as black sheets and acids are still very high, and show no indication of a decline in the meantime. The market for black sheets is seasonably quiet but renewed buying is expected next month. Blue annealed grades continue in good demand with quotations firm. The sheet bar situation is unchanged, a shortage still exists and prices continue firm.

In the United States market, export business continues to be the main stay, but there are signs of a material increase in domestic buying. The buying of the Allied countries is heavy and promises to be for months. Large orders for rails, barb wire and shell steel have been placed; the demand for rails from Russia being particularly heavy. Quotations continue firm on most steel products. Bessemer billets have declined \$2 and are now quoted at \$40 per ton, while open-hearth and forging billets are unchanged at \$42 and \$69 per ton Pittsburgh, respectively. Wire rods are firmer at \$55 per ton Pittsburgh. Steel

bars and shapes are unchanged at 2.75c and 2.50c but tank plates are higher at 3.50c Pittsburgh.

#### Pig Iron

Although the consumption of steel making grades of pig iron continues on a large scale, the market is not greatly affected as the majority of the steel companies produce their own pig iron. On this account the market is dull as consumers of foundry grades are only buying to meet immediate requirements. The situation is unchanged and prevailing prices are given in the selected market quotations.

#### Scrap

Prices of old materials have still a downward tendency due principally to the weakness in the metal markets and also to light demand. Scrap copper, brass and composition materials are weaker and have declined  $\frac{1}{2}$ c per pound, while zinc is also lower at 8c per pound, having declined 1 cent. Heavy melting steel although in good demand is a shade weaker due to an increase in supplies; it has declined 50c per ton. Prevailing prices are given in the selected market quotations.

#### Machine Tools

Orders for shells continue to be the chief feature of interest in the machine tool business. Some contracts have been recently placed while others are pending on large shells principally of 9.2 in calibre. On this account there have been some interesting inquiries received by local dealers principally for heavy duty lathes, drills etc., and some nice business is anticipated. There is a decidedly easier tendency in the market with regard to prices of second-hand tools. In the United States several large houses who deal almost entirely in second-hand machine tools have reduced their prices on equipment of this character by 25 to 30 per cent. The reduction applies to practically all kinds of used tools with the exception of plain and universal grinders and milling machines, for which there is still a big demand. This development in the market has been caused by a falling off in demand and increase in supply, the latter being due to the fact that several large concerns who are unable to secure further contracts for shells have no further use for the equipment. No weakness has developed in prices of new tools as makers are so well sold ahead, there is even a tendency for higher prices on some tools, particularly grinders for which there is a heavy demand.

#### Supplies

The market continues firm but prices are unchanged except for a few lines. A change in discounts of carbon drills and reamers has been made on some lines while others are unchanged. The

new prices are slightly lower which is a favorable indication of the trend of the market. Turpentine and linseed oil have both made a sharp advance, the former due to a reaction in the market in the south and the latter on account of firmness in the flax seed market.

#### Metals

Although the metal markets continue to have a weak tendency, declines are not so general as those registered during the past two or three weeks. The markets however are dull and are characterized by lack of demand. There are no new developments in the copper situation and quotations continue nominal, being based almost entirely on offerings by second-hands. The tin market is stagnant and little interest is being shown in this metal. Spelter has reached a point where consumers are beginning to show a little more interest, but the market is still weak and lower. The lead market is dull and unchanged while there is nothing of particular interest to note in either antimony or aluminum. Solders are also unchanged.

**Copper.**—The market is dull with sellers devoting their time to filling orders already booked. The outlook for copper is good but unless a buying demand develops in the near future it is probable that price concessions will be generally offered. No material decline however may be expected, as all large producers are sold up to practically the end of the year and the demand for copper will be extremely heavy for a long time to come. Quotations are unchanged and nominal at 29 $\frac{1}{2}$ c per pound.

**Tin.**—The market is dull due to lack of demand, sellers reporting an unusual absence of inquiries. The tin market has declined in London on spot metal, while heavy June deliveries have weakened the market in New York. Tin has declined locally and is quoted at 44c per pound.

**Spelter.**—The decline in the market continues. Consumers are still showing little or no interest in the market and producers are not anxious to sell. The lower level of prices however is beginning to interest galvanizers, but little business has resulted so far. Quotations are lower at 13 $\frac{1}{2}$ c per pound.

**Lead.**—The market is very dull but the "Trust" price has been maintained at 6.50c New York and the outside market are a shade lower for both spot and futures. The demand continues light with consumers delaying buying. Lead is unchanged at 8 $\frac{3}{4}$ c per pound.

**Antimony.**—The market is very dull and prices lower and nominal at 24c per pound.

**Aluminum.**—The market is quiet and prices have a weaker tendency although they are unchanged in the meantime at 67c per pound.

**Solders.**—Quotations are unchanged but may decline further unless the tin market reacts. Guaranteed is quoted as 28 $\frac{1}{2}$ c and strictly at 26 $\frac{1}{2}$ c per pound.

#### AUSTRALIA BUYS FREIGHTERS

W. M. HUGHES, Premier of Australia, who has been in London for some time past, has solved the difficulty of a dearth of ships for moving the Australian harvest by going into the market and purchasing 15 large steamers, which will be renamed and operated by the Australian Government as the Commonwealth Government line. The vessels purchased are the Strathendrick, 4,379 tons; Strathavon, 4,403 tons; Strathairly, 4,326 tons; Strathleven, 4,396 tons; Strathdee, 4,409 tons; Strathspey, 4,432 tons; Strathgarry, 4,398 tons; Strathdeg, 4,338 tons; Strathesk, 4,336 tons; Strathearn, 4,419 tons; Ardangorm, 3,570 tons; Ardanmohr, 4,554 tons; Vermont, 4,271 tons; Daltonhail, 3,534 tons; and Kirkoswald, 4,021 tons. The price is believed to approach ten million dollars. The ten Strath ships, were purchased from Burrell & Son.

British shipowners ask what their position will be in competition if these Australian State-owned boats are to be exempt from British income tax and excess profits of taxation. Also, have the British Government who now control all shipping, finally assented to do the same with Canada and the other Dominions that contemplate similar semi-Socialistic adventures? Many of these vessels are now employed on Government war business, and they cannot be available for Australian wheat cargoes until the Imperial Government has done with them.

Australia's purchase of a fleet of fifteen steamers to handle its wheat crop is not at all likely to be emulated by the Canadian Government. The conditions which obtain in the two Dominions being reckoned wholly different. At one time Canada had some difficulty in securing the necessary ocean tonnage, but this has been largely overcome until now. Between twenty and twenty-five million bushels per month are going forward.

On the other hand, Australia's crop movement has been greatly retarded, if not prevented, because of inability to secure ships. The trip is usually long with little offering by way of return cargoes, while the rate quoted by the Commonwealth Government was low, at a time when tonnage is scarce, anyway. These conditions necessitated the State-owned fleet now acquired.

A Canadian merchant marine has been suggested, and may come as a future development, but the grain crop is already being moved with reasonable ex-

pedition and sufficient ships for the purpose have, so far we understand been available.

### COPPER AND SPELTER PRICES DROP

COPPER and spelter continue to decline abroad. Futures and spot copper declined £6 in London on July 7, and spelter was off £2 10s. It is difficult to forecast the effect the recent slump in copper prices abroad will have as sales have been few and far between. Second hands are offering copper several cents a pound below the pegged price of the large agencies.

Certain large agencies viewed the further sharp decline in copper prices with indifference, but there is no getting around the fact that some sort of a readjustment between London and American prices will have to be made. London will either have to bring its prices up

closer to New York prices, or domestic producers will have to lower theirs to correspond more closely with London.

The quotation for spot copper in London is now below 20 cents a pound, with quotations of agencies and second hand dealers in this New York ranging all the way from 26 cents to 29 cents a pound. There is very little change in the domestic copper market. Few sales are being made with production going on at an unprecedented rate. Quotations are regarded as nominal.

### AUSTRALIA LOOKS AHEAD

IT is announced that William Morris Hughes, Premier of Australia, before departing for Australia by way of South Africa, completed with the British Government a plan for marketing the manufacturers of Australia in Great Britain instead of, as before the war, in Germany and other countries.

Mr. Hughes also conferred with representatives of South Africa, the West Indies and India on the subject of the sugar industry, with regard to the control of that industry after the war. The plan discussed provides for the prohibition of the importation of sugar from countries enemy to Great Britain for five years after the war and that thereafter sugar imported from enemy countries will be subject to a general tariff plus a fifty per cent. surtax, while sugar from neutrals will also be subjected to a surtax wherever neutrals decline to enter into reciprocal tariff arrangements.

The scheme will concede to the Allies a preference of 12½ per cent., and grant the sugar grown in the British Empire a fifty per cent. preference. Mr. Hughes also recommended a bonus to stimulate the growth of sugar in Great Britain.

## CANADIAN COMMERCIAL INTELLIGENCE SERVICE

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

# INDUSTRIAL <sup>A</sup><sub>N</sub><sup>D</sup> CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

## Engineering

**Dartmouth, N.S.**—The Imperial Oil Co., Montreal, contemplate erecting a large refinery here.

**Sorel, Que.**—The Longborough Mining Co. propose building a mica factory here to cost about \$10,000.

**Vancouver, B.C.**—The Colonial Lumber and Paper Mills will build a pulp and paper mill at Quatsino, B.C.

**Toronto.**—The William Davies Co. have taken out a permit for the erection of an ice-making plant at Front street east, which is to cost \$45,000.

**Renfrew, Ont.**—Fire on July 15 destroyed part of the O'Brien plant near here. The damage is estimated at about \$100,000, which is covered by insurance. The plant will be rebuilt.

**Porcupine, Ont.**—The Northern Canada Power Co. propose installing in their power plant at Wawaitin a 4,000 h.p. water turbine and generator.

**Beauceville, Que.**—Marcoux & Poirier's foundry, which was recently destroyed by fire with a loss of \$12,000, will be rebuilt and new machinery installed.

**Medicine Hat, Alta.**—The Alberta Foundry & Machine Co. will build an addition to its plant, 120 x 160 ft. to include an iron foundry and machine shop to cost \$20,000.

**The Northern Canada Power Co.** is installing at Sandy Falls, B.C., a 2,500 h. p. Canadian General Electric generator, direct connected to an I.P. Morris water wheel, with surge tank wooden stave penstock, and controlling valves.

**Niagara Falls, Ont.**—The new plant of the Canada Nickel Smelting & Refining Co. at Chippawa is practically finished, and will likely be in operation within a few weeks. It will be the first nickel refining plant to use Niagara power.

**The Armstrong-Whitworth Co. of Canada,** at Longueuil, Que., will instal two 6-ton "Heroult" electric furnaces for making forged tires, wheels and axles from cold scrap. These are in addition to the one 3-ton furnace used for making tool steel.

**St. John, N.B.**—The C. P. R. will spend \$100,000 on improvements to its yards at St. John, N.B., including the

erection of a coal-handling plant, a new water tank of 200,000 gal. capacity, etc. J. M. R. Fairbairn, Montreal, is assistant engineer.

**Montreal.**—Announcement is made that the new sulphuric acid plant of the Consolidated Mining & Smelting Co., Trail, B.C., has been completed, and will be started up very shortly. It will manufacture the acid as a by product of the smelter fumes. The company's other extension includes the new zinc plant recently started up and a copper refining plant.

**Ottawa, Ont.**—That erection would start immediately of the big steel plant which the United States Steel Corporation plans to erect at Ojibway, near Windsor, Ont., was the statement made by Wallace Nesbitt, K.C., recently. Mr. Nesbitt was in the city arranging certain departmental matters in connection with the going ahead of the work. The company over two years ago secured a large tract of land at Ojibway, but little has been done up to the present to be erected will cost about \$25,000,000.

## Electrical

**Petrolea, Ont.**—As result of a Hydro meeting held in Courtright the Village Council will make request to the Hydro Commission for its estimate of a plant that will serve the needs of Courtright for light and power.

## Municipal

**Calgary, Alta.**—The city council propose to install a sewage disposal plant at a cost of \$300,000.

**Watford, Ont.**—A by-law will be submitted to the ratepayers on Aug. 1, to raise \$10,000 for a hydro-electric plant.

**Petrolia, Ont.**—A by-law will be voted on by the ratepayers on July 31, to authorize a loan of \$1,700 to the Lambton Flax Co.

**Prince George, B.C.**—An expenditure of \$150,000 is contemplated on extensions to the waterworks, and installation of an electric light system.

**Kingsville, Ont.**—The by-law authorizing the expenditure of \$16,000 for

improvements to waterworks system has been passed. A new pump will be included among the improvements.

**Cobourg, Ont.**—Plans are out for a new intake pipe to be installed at Cobourg by the Ontario Hydro-electric Power Commission, Central Ontario System. It is to be a 24-inch pipe, extending 900 feet into the lake. With the filters now in use this will give Cobourg a splendid water supply. It is expected that the work will be carried out this summer.

**Stamford Village, Ont.**—By a vote of 100 to 34, the ratepayers of Stamford Township on July 10, requested the Provincial Government to take over and operate the plant of the Ontario Distributing Co. in Stamford and Niagara townships pending the passing of legislation that will give the township the right to operate its own lighting plant under Hydro-Electric supervision.

## General Industrial

**Montreal.**—The J. J. Joubert Co., will build a factory at a cost of \$8,000.

**Sherbrooke, Que.**—The Canadian Connecticut Co. contemplate building an extension to their plant.

**St. Jerome, Que.**—The Regent-Spinners, Ltd., contemplate building a mill here.

**Moncton, N.B.**—The Atlantic Underwear Co. propose building an extension to their factory.

**Toronto, Ont.**—The Canadian Bag Co. of Montreal will build a factory here to cost about \$40,000.

**Montreal.**—The Dominion Textile Co. will build an extension to the mill at Montmorency Falls, Que. A. Byers & Co., Montreal, are the general contractors.

**Hamilton, Ont.**—The Appleford Counter-Check Book Co., have been granted a building permit for an addition and alterations to their factory on Stirtor street, to cost \$7,500.

**St. Thomas, Ont.**—The Monarch Knitting Co. are asking the city to provide a loan of \$30,000 for the erection of a hosiery factory, and a by-law is to be submitted to the ratepayers early in August.

# Thread

# Miller

An Ideal  
Machine for  
9" Shells.

## Specifications

Net Weight	-	-	-	3300 lbs.
Weight Crated	-	-	-	3400 lbs.
Weight Boxed	-	-	-	3500 lbs.
Shipping Dimensions	-	-	-	108 c. ft.
Time per operation	-	-	-	16 mins.
Threading or Recessing Base, Threading Nose	-	-	-	10 mins.

**WHAT** importance do you place on the internal threads of your shells? How about the machine that does that threading? Illustrated here is a thread miller for 9-inch shells. We do not ask you to buy it—yet, we want you to study it, look its features over and we feel that its quality and price will convince you that it is a machine of exceptional merit.

The shell is carried between two conical surfaces in the interior of the mandrel, thus ensuring the thread being milled perfectly true with the axis of the shell. By this method the shell is held much firmer and truer than by

collet chucks. The master screw is chased on the outside of the mandrel. The milling head is carried in moveable carriage and both slides are moved up to positive stops and locked, so that the thread is milled exact.

The A. R. Williams Machinery Co., Ltd.

64-66 Front Street West, Toronto

## WHO KNOWS A BETTER?

"Our real reason for using Geometric Tools is the service they give—and we use them exclusively."

So says a Shop Foreman. He particularly mentioned a job, then in hand, of threading a piece  $3\frac{3}{4}$  in. diameter,  $11\frac{1}{2}$  threads per inch, to shoulder. Between 400 and 450 such pieces were threaded daily. Each threaded piece an exact duplicate—correct in every particular.

Geometric Self-opening and Adjustable Screw-cutting Die Head.

Geometric Adjustable Collapsing Tap.

Whether it is an outside thread or an inside thread, of whatever diameter, length, pitch or form, a Geometric Screw-cutting tool will produce it. Whatever the make of your Screw Machine, a Geometric will fit it.

Let us know the class of thread-cutting that you have to do, and we will send booklet describing the type of tool best suited to it.

## New Incorporations

**The Cracroft Copper Mines**, of Vancouver, have been incorporated at Victoria, B.C., with a capital of \$100,000.

**Canadian Comstock Co.**, has been incorporated at Ottawa with a capital of \$40,000 to carry on business as contractors and engineers at Montreal. Incorporators, A. Wainwright, A. H. Elder and F. W. Hackett all of Montreal.

**Dominion Linens Ltd.**, has been incorporated at Ottawa with a capital of \$550,000 to carry on business as weavers, spinners, etc., at Guelph, Ont. Incorporators, D. M. Lanson, T. W. Yyon and William Berry all of Guelph, Ont.

**The Modern Tool Mfg. Co.**, has been incorporated at Ottawa with a capital of \$100,000 to make machinery, gauges, tools, shells, etc., at Montreal. Incorporators, T. Y. Sarault, L. P. Renaud and J. Peloquin all of Montreal.

**Gunn Richards, & Co.**, has been incorporated at Ottawa with a capital of \$50,000 to carry on business as production and consulting engineers at Montreal. Incorporators Thomas Mr. Fyshe, John L. Reay and Charles G. Ogden all of Montreal.

**Metal Spray Ltd.**, has been incorporated at Ottawa with a capital of \$10,000 to manufacture metals, metal powders, chemicals, etc. Head office at Montreal. Incorporators, Louis B. Schwary, George H. Spencer and Constantine A. O. Gorman all of Montreal.

**The Turner Wheel & Machine Co.** has been incorporated at Ottawa, with a capital of \$20,000, to manufacture automobiles and parts thereof at Windsor, Ont. Incorporators are: Harry E. Guppy, William T. Turner and George F. Turner, all of Windsor, Ont.

**The Manitoba Steel Foundries, Ltd.**, has been incorporated at Ottawa with a capital of \$300,000 to carry on the business of steel and iron founders, mechanical engineers, etc., at Winnipeg, Man. Incorporators are Peter J. Smith, Arthur M. Tirbutt all of Winnipeg.

**The Canada Broom & Brush Co.** has been incorporated at Toronto, with a capital of \$15,000, to manufacture brooms, brushes and woodenware, at Ridgetown, Ont. Provisional directors are: W. Purdy, A. V. Farnsworth and J. M. Sheldon, all of Ridgetown, Ont.

**The Canadian Conley Frog & Switch Co.** has been incorporated at Toronto, with a capital of \$150,000, to manufacture track equipment and railroad supplies at Port Arthur, Ont. Incorporators are: W. F. Langworthy and G. A. McTeigue, all of Port Arthur, Ont.

**Booth Fisheries Co. of Canada**, has been incorporated at Ottawa with a capital of \$1,000,000 to carry on the business of fish curing and packing etc. Head office is at Toronto and the incorporators are William A. T. Case, James B. Taylor and W. M. Smith all of Toronto.

**Richelieu Industrial Co.** has been incorporated at Ottawa, with a capital of \$45,000, to operate saw mills and make machinery of all kinds. Head office at Montreal. Incorporators are: Salluste Lavery, of Longueuil, Que.; Henri Prieur and Thomas Robillard, of Montreal.

**The Woodstock Reinforced Concrete Post Co.** has been incorporated at Toronto, with a capital of \$40,000, to manufacture concrete posts and products of all kinds, at Woodstock, Ont. Provisional directors are: B. Blair, J. Fairbanks and D. Thomson, all of Woodstock, Ont.

**The Hoover Co.** has been incorporated at Ottawa, with a capital of \$100,000, to acquire the Canadian rights of the "Hoover" process of purifying water and to manufacture plants. Head office at Montreal. Incorporators: Louis Gosselin, Eugene Provost, and J. A. Beauchamp, all of Montreal.

**The Exeter Creamery Co.**, has been incorporated at Toronto with a capital of \$40,000 to manufacture milk products and to establish a public cold storage plant at Exeter, Ont. Provisional directors are William G. Medd, George Jaques and F. Bruce Medd all of Usborne-Township, Ont.

**The Algoma Construction & Engineering Co.** has been incorporated at Toronto, with a capital of \$100,000, to manufacture steel, nickel and any other ore products, charcoal, coke and by-products, etc., at Sault Ste. Marie, Ont. The provisional directors are: Alexander Taylor, R. E. Nicholson and J. G. Gibson, all of Toronto.

**Leaside Munitions Co.**, has been incorporated at Ottawa with a capital of \$250,000 to carry on business as mechanical engineers and to manufacture shells, bombs and fuses, etc., at Toronto. Incorporators are William A. T. Case, James B. Taylor and Charles L. Valens all of Toronto.

**Remington U.M.C. of Canada** has been incorporated at Ottawa, with a capital of \$25,000, to manufacture cartridges and munitions, and to take over the business heretofore carried on by the Remington Arms-Union Metallic Cartridge Co. at Windsor, Ont. Incorporators: John A. Worrell, William D. Gwynne and John S. Smith, all of Toronto.

**The Metals Coating Co. of Canada** has been incorporated at Ottawa, with a capital of \$200,000, to acquire the rights of "The Schoop Process of Metallic Deposition" and to manufacture mechanical specialties of all kinds. Head office at Montreal. Incorporators are: A. A. W. Plimsoil, Reigner Brodeur and Adolphe Chouinard, all of Montreal.

## Tenders

**Outremont, Que.**—Tenders will be received till August 2, for the construction of an incinerator. Specifications and forms of tender may be obtained at the office of the city engineer.

**Ottawa, Ont.**—Tenders for incandescent lamps, public buildings, Ottawa, Ont., will be received until July 24. Specification to be seen on application to Thos. A. Hastings, clerk of works, Postal Station "F," Toronto; to R. L. Deschamps, overseer, Dominion Bldgs., Montreal, and to the chief architect, Department of Public Works, Ottawa.

**Ottawa, Ont.**—Tenders addressed to J. W. Pugsley, secretary, Department of Railways and Canals, Ottawa, Ont., will be received up to August 7, for the construction and erection of passenger station at Halifax, N.S. Plans, specifications and blank form of contract may be seen at the offices of the following: Chief Engineer, Department of Railways and Canals, Ottawa, Ont.; Chief Engineer, Canadian Government Railways, Moncton, N.B. Superintending Engineer, Halifax Ocean Terminals, Halifax, N.S.; Ross & Macdonald, architects, Montreal and Toronto. Contractors who wish to obtain plans and specifications temporarily for their own use, may obtain same from Ross & Macdonald, Montreal, on depositing with them a certified bank cheque for \$100, which will be refunded on the return of the plans and specifications to them.

**Assiniboia, Sask.**—Tenders will be received up to August 8, for the supply and delivery of the following machinery and materials: (A)—For the supply, delivery and erection of an 150 h.p. internal combustion engine; (B)—For the supply and delivery and erection of generator, exciter, switch board, and other apparatus; (C)—For the supply, delivery and erection of pumps, motors, piping and air compressor; (D)—For the supply and delivery of two pneumatic storage tanks; (E)—For the supply and delivery of one oil storage tank; (F)—For the supply and delivery of poles, wire and line material; (G)—For the supply and delivery of approximately 17,500 feet of 4 in., 6 in. and 8 in. steel pipe, or cast-iron pipes and specials; (H)—For the supply and delivery of 20

# Aikenhead's

# DUMORE GRINDER

This GRINDER has become known as the most efficient portable grinder. Wherever there is grinding to be done it is as valuable as the services of one or two extra men.

The DUMORE Portable Grinder. The only small grinder giving wheels the correct surface speed. Speed, 30,000 R. P. M.

The DUMORE does all kinds of grinding, longitudinal, cylindrical, internal and other hard-to-get-at jobs. It is equipped with a rest for grinding cutters, enabling the operator to grind his cutters right on the Miller Arbor, whether angular, straight or spiral.

Internal Grinding with the DUMORE. The internal attachment is easily put on or removed.

## Aikenhead Hardware Limited

The best way for you to know how much the DUMORE Portable Grinder will mean to you will be to try one out. Let us ship you a DUMORE.

## Taking it Easy in the Boss' Time

Of course they've "rung in." Bless your heart they did that long ago, right on time, away down at the factory entrance.

What about the time they lose in actually getting to work?

Don't say "I should worry, they're working on piece-work—the loss is their's." It isn't. You want your employees at work on time, turning out as much of your product as possible in order to keep your overhead down.

Of course, if your employees are working on a regular weekly time payment basis, their delay in actually getting to work, after they have rung in, is even more serious. Then there is a direct wage loss as well as a loss in overhead expense for light, power, heat, etc.

How are you going to cure this? With an International Time Recorder.

Remember, we are the largest makers of Time Recorders in the world. Our Canadian plant can equip you with a system to suit any requirements.

## The International Time Recording Co. of Canada, Limited

70 Bond St., Toronto

## The Metals Coating Co. of Canada, Ltd.

Versailles Building, 90 James St.  
MONTREAL, CANADA

A machine gun making its ammunition from Reeled Wire, and coating objects by bombarding with minute plastic particles of metal. The Schoop method of Metallic deposition, any object and any size coated with a positive adhesive and homogeneous coating with any metal for any desired thickness.

Solves one of the greatest problems heretofore confronting the structural engineer, because it produces on iron or steel a permanent coating not susceptible to corrosion.

Carbons can be coated with copper, etc.

For full information write for booklet "D".

hydrants, 29 gate valves and boxes; (J)—For the erection of power station; (K)—For the supply, delivery and installation of heating plant. Complete sets of plans and specifications may be seen at the office of the consulting engineers, Murphy & Underwood, Saskatoon, and at the secretary-treasurer's office, Assiniboia, Sask.

**Saskatoon, Sask.**—Tenders are being called until July 26 for a high pressure water main system.

**Toronto, Ont.**—The Board of Education are calling tenders for motor generator set, program clocks and other electrical equipment, for the High School of Commerce. Specifications, etc., may be seen at the office of the clerk of supplies.

**Toronto.**—Tenders will be received by chairman Board of Control, City Hall, Toronto, up to Aug. 1, for the supply and delivery of air brake equipment, step and door operating mechanisms, gears and pinions. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

**Toronto.**—Tenders for the erection of a court house at Sault Ste. Marie (separate tenders are required for the heating and ventilating and plumbing and electric wiring) will be received up to July 21. Plans and specifications can be seen at the office of the sheriff, Sault Ste. Marie, and at the Departments of Public Works, Ontario Parliament Buildings, Toronto.

## Contracts Awarded

**The Pas, Man.**—The Town Council have awarded the general contract for the construction of a sewage plant to the North Western Construction Co., Regina, at \$4,490. Engineers, Murphy & Underwood, Saskatoon.

**Dauphin, Man.**—S. Brown, a Winnipeg contractor, tendered the lowest bid for the construction of the new court house at Dauphin. Cotter Bros., also of Winnipeg, were the lowest bidders for the plumbing and heating contract in the new court house, their bid being \$8,829 for the one-pipe system and \$9,692 for the two-pipe system. J. H. Bossons, of Dauphin, is the architect.

## Trade Gossip

**The Wilt Twist Drill Co. of Canada,** Walkerville, Ont., have increased their capital stock to \$500,000.

**The H. A. Drury Co.,** Montreal, are North American agents for Sanderson

Bros., & Newbould, of Sheffield, England, and not Montreal agents only, as would be inferred in a catalogue notice which appeared in July 6 issue of Canadian Machinery.

**Railroad Freight Rates.**—Judgment has been handed out by the Railway Commission in the eastern freight rates case, which has been before the board for the last two years. The all-round increase asked for by the railways is not granted, but each rate is considered on its merits, the increases varying according to localities and commodities concerned.

**Toronto, Ont.**—It is reported that the Federal Dyestuff & Chemical Corporation, 30 Pine street, New York, with a plant located at Kingsport, Tenn., proposes to establish another in Western Ontario, in conjunction with some Toronto capitalists, for the manufacture of dyestuffs, etc. Walter A. Guile, Jr., vice-president of the Federal Dye Corporation, is in charge.

**Railway Commission.**—The Dominion Government has appointed a commission to enquire into the railway situation in Canada. The members of the Commission are Alfred H. Smith, President of the New York Central Lines; Sir Henry Drayton, Chairman of the Board of Railway Commissioners, and Sir George Paish, a Financial Adviser to the British Government.

**Promote Asbestos Industry.**—The Eastern Townships Associated Boards of Trade, have adopted a resolution calling upon the Quebec Provincial Government to take immediate steps to conserve its valuable asbestos asset to the limit, by the introduction of legislation which will force the manufacture within the province of finished articles, into which asbestos enters.

**Montreal Automobile Trade Association** makes the announcement that the 1917 Motor Show will be held from January 13th to 20th inclusive. The New York show is announced for January 1st to 8th, and the Chicago show from January 27th to February 3rd. The latter dates will avoid the clashing of the Montreal and Chicago shows, as has been the case for several years past.

**Iron Ore Shipments.**—Bradstreet's says that iron ore shipments through the Soo Canal during June totalled 9,507,000 tons. This is a new high record in history. Since the opening of navigation 19,615,000 tons have passed through en route east to United States and Canadian plants. These figures indicate two things, the enormous activity of the iron and steel industries, and the busy season for lake freight companies.

## 3 BIG REASONS WHY YOU NEED

# PURO

(MADE IN CANADA)

1. Puro Sanitary Drinking Fountains will give you a better water supply cheaper.
2. Puro will cut your water bills 15% to 35%.
3. PURO will safeguard the health of your employees and raise the standard of efficiency.

Are not these reasons enough? Then why hesitate longer? PURO equipment is not expensive—the first cost is low and the up-keep nothing. Easily attached; positively fool-proof. Let us make you a special proposition for a try-out in one of your departments. Write us now—today—giving us the number of men: an inquiry will cost you nothing.

## "Barnes-made" SPRINGS

are unusual in service and wear

They are the result of sixty years' experience, unsurpassed equipment and highly skilled workmanship

A trial will convince you that "Barnes-made" Springs are the best buy.

Established 1857

THE WALLACE BARNES COMPANY

218 South St., Bristol, Ct., U.S.A.

Manfrs of "Barnes-made" Products  
Springs, Screw Machine Products, Cold Rolled Steel and Wire

tional Communication Co. held recently in London, England, Godfrey Isaacs, who presided, said that Mr. Marconi had authorized him to say that in the very near future he would introduce a new, independent and very simple apparatus, to be worked from the bridge of a ship by an officer, which should put an end to all danger of collision in darkness or fog. There was little doubt that every sea-going vessel would be equipped with this invention.

### Blast Furnace for British Columbia.—

A movement is on foot to establish a blast-furnace plant in British Columbia. At a recent meeting of representatives of the Vancouver Chamber of Mines and the Intermunicipal Industries Committee, and others, a resolution was passed for the employment of a staff of engineers to report in four months on the supplies of iron ores accessible to the coast, and on the feasibility of establishing a smelter for such ores on the coast. At present there is only one small Bessemer steel casting plant in British Columbia, but there are a number of copper smelters.

The Thomson Porter Cataract Co., headed by T. Kennard Thomson and the Hon. Peter A. Porter, has applied for a Dominion charter, with rights to construct in the rapids of the Niagara River, below the falls, the Canadian half of an international dam to raise the water 100 feet and develop, as stated, 2,000,000 horse-power. One-half would go to Ontario and the other half to New York. Without any Government aid, the company says it expects to expend \$80,000,000 or \$100,000,000 and undertakes to submit plans and specifications for the approval of the Dominion and Ontario Governments.

The Storey Pump & Equipment Co. have secured a contract for two 6 in. two-stage Morris pumps with electric motors, from the corporation of Niagara-on-the-Lake. They have also supplied two similar pumps for water supply at Camp Borden. Among other orders of recent date are the following: Gutta Percha & Rubber Co., 16 x 4 x 10 in. Worthington duplex hydraulic pump; Goldie & McCulloch Co., 4 x 12 in. Deane duplex hydraulic plunger pump, for 1,500 lbs. pressure; several pumps for the New Imperial Oil building; five manganese steel-lined Morris centrifugal pumps for the Cobalt Reduction Co.; two three-stage, high duty motor-driven centrifugal pumps for Cordova Mines, Ltd., etc.

**Hawkrige Brothers Company**

303 Congress St., BOSTON, MASS.  
U.S.A.

**Substitute for Gasoline.** — Arthur D. Little, a well-known chemical engineer of Boston, in a lecture delivered recently before the Vancouver branch of the Canadian Society of Civil Engineers, predicted that ethyl-alcohol would before long be very widely used as a substitute for gasoline for internal combustion engines. Not, because the price of gasoline was being inflated by manipulation, but due solely to the fact that the manufacture of automobiles and other vehicles driven by internal combustion engines was increasing so rapidly that the supply of gasoline was fast becoming too small. Ethyl-alcohol, could now be produced very cheaply from sawdust and other lumber waste, and he believed that eventually British Columbia would derive considerable revenue from that source.

## Personal

**A. E. Boyle** has been appointed secretary of the Winnipeg Board of Trade in succession to Dr. C. N. Bell who has resigned after eight years service.

**Lieut.-Colonel Noel Marshall**, of the Standard Fuel Co., Toronto, and chairman of the executive of the Canadian Red Cross, has sailed for Canada on the Baltic.

**D. O. Lesperance**, ex-M. P.; **D. H. Pennington** and **Alfred S. Gravel** have been appointed harbor commissioners of Quebec City. Mr. Lesperance will be the chairman.

**Major T. C. Irving, D.S.O.**, of Toronto, now serving at the front with the Canadian Engineers, was married in Kent, recently, to **Jessie**, daughter of **Angus Murray**, of Toronto.

**Sir Donald Mann** is in the West inspecting the Canadian Northern System, and is accompanied by Messrs. **Loomis**, **Platten** and **Coverdale**, of New York. Mr. **Loomis** is vice-president of the Delaware & Lackawanna Railway, and the others are connected with big financial institutions interested in the C. N.R. They are making the trip for the purpose of inspecting the property and the territory which the lines serve.

**Captain Eugene McCormick**, mate of the Canadian lightship **Falken**, which is stationed at the Southeast Shoal, Lake Erie, died at his home, Amherstburg, on July 5. His illness is said to have resulted from exposure and hardship while bringing the lightship from her station to Amherstburg in December, 1914. The boat arrived with the pilot-house windows broken by the sea, and the hull and upper works heavily coated with ice. Capt. McCormick was born on Pelee Island in 1849. He was master of

**Graphite Sheet Lubricator.**—The Strong, Carlisle & Hammond Co., Cleveland, Ohio, are distributing to the trade a series of leaflets describing the "Randall" graphite sheet lubricator for all kinds of machinery and wheel journals on cars and locomotives, etc. Directions are given for applying this lubricator and a number of illustrations show various types of bearings that have been equipped with it. A sample together with literature can be obtained on application by any dealer sufficiently interested.

## Book Review

**The Engineer's Year-Book**, by H. R. Kempe, Crown 8vo. (7 in. x 5 in. x 2 1/4 in.) limp leather, gilt 1,500 pages, specially engraved illustrations. Published for the proprietors by Crosby, Lockwood & Son, London, England. Price \$5 net. This is the twenty-third edition of Kempe's "Engineer's Year Book," of formulae, rules, tables, data and memoranda for 1916. It is so well known as to hardly need any introduction, and it is generally conceded to be one of the most useful reference books for engineers published. This edition has been enlarged, corrected and brought right up to date, and contains a large amount of new information covering the latest engineering practice. It covers a wide field and contains a great deal of valuable and reliable information for the use of engineers in the various branches of the profession, manufacturers, work's managers, draftsmen and power users. The Year Book forms a compendium of the modern practice of civil, mechanical, electrical, marine, gas, and mine engineering. There are thirty-five sections, each devoted to some branch of engineering, contributed or revised as the case may be, by well-known authorities on the different subjects, a sufficient guarantee of the reliability of the information contained. A creditable feature of this publication is the way in which information on each subject and covering such a wide field has been arranged in so compact a form. The tables, of which there are a large number, are well arranged and the formulae easy to follow, while the descriptions of machinery and apparatus are written in a comprehensive manner. The illustrations which are exceptionally clear have been produced from specially prepared engravings. The book which is printed on fine paper has a 60-page index, and is bound in attractive red covers.

# Casting 8 in. H.E. Shell Ingots and Forging the Rough Shells

## Staff Article

*In our June 29 and July 13 issues are to be found articles descriptive of the machining and completion of 8-inch high explosive shells in a Canadian metal-working plant. The present article deals with their inception from the raw material in two other plants, and demonstrates as in the machining processes the same high degree achievement in the direction of both quality and quantity output; the casting and forging conditions being if anything the more exacting and irksome when compared with the machining, as might be anticipated.*

**D**URING the earlier stages of the war, the demand was very largely for the smaller type of high explosive and shrapnel shells, but the conditions arising from the special nature of modern trench warfare, required that the heavier types of explosive shells be used in constantly increasing numbers. To meet the requirements of the Imperial Government, many Canadian manufacturers have been for several months installing and preparing equipment. Some plants as a matter of fact have been shipping large shells for a considerable period now, while others are rapidly reaching a point where production will only be governed by the supply of raw material and by labor conditions. As the original British specifications called for the body of the shells to be made from acid open-hearth steel, the billets now being used are generally produced by this method. The brief description here given outlines the process of casting and forging the 8-inch shell blanks, in preparation for the succeeding machining operations.

### Preparing and Melting the Charge

To meet the requirements of shell specifications, it is necessary that the various metals comprising the charge

shall be so proportioned that the molten mixture as it flows into the ladle or moulds shall embody the desired physical properties. Under normal conditions

the scrap is first analyzed. In shell steel manufacture, the bulk of the scrap has already been in the furnace for shell making purposes, and, therefore, it be-

FIG. 2. POURING THE INGOT MOLDS.

comes much easier for the melter to calculate his charge.

### Constituent of the Charge

The plant here featured, is now using in a 20-ton charge from 7,000 to 7,500 pounds of pig; 13,000 pounds of shell head scrap; 7,600 pounds of plate scrap, and about 11,000 pounds of crop ends from the tops of the previous ingots. These with the addition of iron ore, silicon and manganese bring the total charge up to between 38,000 and 42,000 pounds, or approximately 21 tons. Of the pig iron (which is about 20 per cent. of the total charge), 75 per cent. is placed in the furnace first, and as this begins to settle, the shell scrap, plate scrap, and crop ends are added. When these have become partly melted, the remaining 25 per cent. of pig is placed in the furnace. The time required to melt the charge of about 20 tons is from 4½ to 5 hours; in addition, another hour or so elapses before the molten mass comes to a tapping condition. During this last period, after the graphitic carbon has been entirely burned out, sufficient ore, silicon and manganese are added to bring the molten metal up to the desired quality.

Fuel oil is used to heat the metal, a

FIG. 1. TAPPING THE FURNACE.

burner being placed at each side of the furnace and operating under a pressure of about 45 lbs., with sufficient air to insure proper combustion of the oil gases. These two burners do not operate at the same time, but alternately; the direction of the flame being altered every 20 minutes. This is to permit of proper and uniform heating of the mass of metal, as the action of the burning gases over the top of the charge in different directions, helps greatly to thoroughly mix the large body of metal. Each time the burners are changed, the dampers are regulated so as to allow the burned gases to pass on through the opposite regenerators or checkers and on up the stack. The approximate amount of oil used to melt a charge of about 21 tons, averages some 700 galls; which on eight heats a day from two furnaces, will use up about 5,600 galls. a day, or roughly speaking 35 gallons per ton of metal.

Tests for Carbon Content

When the heat is about ready to tap, tests are made for carbon content by removing a small quantity of the metal from the furnace by means of a long light ladle inserted into the fire chamber. This is poured into a small metal mould, having a cross sectional area of about  $1\frac{1}{4}$  square inches, and is cooled quickly, after which the bar is broken. The trained eye of the melter readily tells him the amount of carbon contained in the steel, by the exposed surface of the fracture. No chemical test is made of a charge until the metal has been poured into the moulds, but during the pouring process a small quantity of the molten metal is taken from the ladle, poured into small moulds and allowed to cool. Drillings from these pieces are then given a laboratory test to determine the various physical properties

contained in each heat; this record being again checked by a second test made by the Government chemists. As each heat is kept separate from the others in its

FIG. 3. SECTION OF MOLD AND CAP.

journey from the furnace to the finished shell, it is possible to make the billet when heating for the forging operation to more closely conform to the desired specifications.

Tapping and Pouring the Molten Metal

When the bath of molten metal has attained the proper condition, the entire charge of over 20 tons is tapped into a large ladle, which has previously been heated by a special oil burner; this being necessary to avoid chilling of the hot metal. The general practice in the making of large steel castings or ingots, is to fill the moulds from a bottom pouring ladle. The mechanism, which controls the flow of the metal, requires to be overhauled after each heat and certain parts renewed, before using the ladle for the next heat. When the melter decides that the molten mass is ready, the stopper connections are placed in the ladle, which is then picked up by a 25-ton Morgan traveling crane, and taken to a position in front of the open-hearth furnace. Fig. 1 shows the large 20-ton ladle (supported by the crane) receiving the metal as it comes down the trough from the furnace. When the ladle is filled, the slag forms a dome-shaped arch over the top of the metal, as can be seen in Fig. 2.

The ladle is now taken to a position above the moulds to be filled. As can be seen in Fig. 2, the moulds for the 8-inch ingots are placed in two rows, and two sections: the one in the foreground being in the centre of the floor and the other on one side farther down the shop. The set in the foreground is usually poured first, as the crane is more easily operated when the heavy load is evenly distributed. When the side section is filled first, trouble is experienced in moving the crane from one mould to another, there being a tendency of the wheels on the opposite side to leave the rails, causing an irregular and jumping movement when shifting from one position to another.

When filling the moulds, the pouring

FIG. 4. PREPARING THE SAND CAPS.

nozzle is kept as close to the opening as conditions will permit, so as to avoid any unnecessary splash when the metal strikes the bottom of the mould. The

of the metal as the billet solidifies. It requires about 15 or 20 minutes for the ingots to become solid, but they are often left in the moulds for an hour or so be-

the ladle is turned completely over, thus permitting the top crust of slag to fall away. While the interior of the ladle is being prepared for the next heat, the stopper rod and graphite connections are being repaired.

#### Cutting Off the Crop Ends

When the ingots have sufficiently cooled, they are removed to the opposite end of the shop, where the crop ends are cut off. This operation is performed on four Bridgeford axle lathes, three of which are shown in Fig. 5. These machines are each driven by a 20 h.p. Canadian Westinghouse motor. The time required to cut off the end averages about ten minutes each. As in all other instances, the amount of crop to be removed is about 20 per cent. of the volume of the ingot.

#### Forging the Eight-Inch Shells

Owing to the extensive scale upon which the manufacture of shells is now being carried on, there are very few factories equipped with the necessary machinery and facilities for the complete process of production, from the cast ingot to the finished shell. In spite of these conditions, however, and because of the thorough co-operation of the different makers, the successful production of shells is being steadily maintained, and increased. When the crop ends of the ingots are cut off, the billets are taken to another plant where they are forged into the rough shell, in readiness for the succeeding machining operations. The billets, 15 at a time, are placed in oil-burning Ferguson furn-

FIG. 5. CUTTING OFF THE CROP ENDS.

successful production of good clean ingots depends largely upon the skill and experience of the man operating the ladle, as proper control of the stream of metal is essential to the economical and rapid production of this class of work. To facilitate operations, the pouring nozzle is kept in such a position that the mouth of the moulds can be clearly seen by the crane operator; which aids considerably in locating the nozzle over each mould.

#### Ingot Output Per Heat

The capacity of the 20-ton ladle will fill approximately 120 eight-inch molds, or 360 four point five-inch moulds. In the case of the 8-inch billets, little difficulty is experienced in pouring the metal; but in order to avoid any possibility of the metal "freezing," it is advisable to have the molten metal very hot when working on the 4.50 ingots; as the time required to fill the 360 moulds averages about one and one-half hours. Under these conditions it is necessary that the nozzles be made of the very best grade of fire brick in order to withstand the intense heat of the metal, and the opening and closing of the stopper 360 times. Owing to a poor nozzle fusing some time ago, this plant had the misfortune to lose an entire heat, which had to be run out on the floor. In addition to the selection of good nozzles, it is important to avoid a "swirl" of the metal when leaving the ladle, as this is injurious to the nozzle and stopper, and also gives a bad surface to the ingot.

As each ingot is poured, the top surface is covered with floor sand to retain the heat, and also to aid in the feeding

fore they are shaken out. By means of special tackle, five ingots are removed at a time, and placed in a pile to cool.

#### Preparing the Ladle and Moulds

When the 8-inch ingots were first being made, the moulds were made similar to those of the smaller sizes; but the type of mould now being used has a solid base, as shown by the sketch, Fig. 3. These moulds are made of grey cast iron, the bore being formed by a core of the proper dimensions. The caps, which are made of 60 per cent. floor sand, 30 per cent. new sand, and 10 per cent. fire clay, are re-enforced by two rings of  $\frac{1}{4}$  inch iron wire, and made in aluminum molds. One man can turn out 175 of these caps a day, when working on the 8-inch, and 300 when working on the 4.5-inch. As shown in Fig. 4, the caps are placed on steel plates, which are afterwards mounted on structural steel cars and run into the drying ovens, where they are subjected to the heat of a coke fire for three or four hours. When placing these on the tops of the moulds, care should be taken to have a good joint, as any fins formed at the top of the metal mould will prevent proper feeding of the metal, and cause slight cracks to develop on surface of ingot.

#### Ladle Refitting

Owing to the injurious effect of the molten metal upon the graphite sleeves and stopper, and also the nozzle, these are renewed for every heat. When the last of the good steel has been run into the moulds, the ladle is taken to the dumping pit, the stopper connections removed and the remainder of the metal and slag allowed to run out; after which

FORGING 8-IN. HIGH EXPLOSIVE SHELLS.

aces and are heated to about 2,100 degs. F., this takes from  $1\frac{3}{4}$  to 2 hours. When the billets are a little high in carbon,

they are allowed to soak a little longer, thus slightly reducing the percentage of carbon.

### Forging Capacity

The 350-ton Wood forging press shown has a capacity of approximately 450 shells per day of 24 hours; and to maintain this production it requires the continuous operation of four 15 shell heating furnaces. When the billets have been heated to the desired temperature, and as uniformly as possible, they are removed from the furnace by means of tongs about 14 feet long, the weight of the billet and tongs being supported by a monorail overhead, which runs from in front of the fire door to the forging press. To insure satisfactory operation, the scale is removed from the surface of the heated billet by means of scrapers. This is not only necessary for the longer life of the dies, but is essential to the uniform drawing of the shell, as the adherence of scale will often tend to produce a forging with eccentric walls. After removing the scale, the billet is rolled to a hole in the block, permitting the nose to drop in, and the billet to stand in a vertical position, when it is gripped by a pair of tongs, which are supported by means of an air hoist, travelling on the arm of a jib crane. By means of the air lift, the shell billet is raised above the die and dropped into position. Two operations are required to complete the shell, forming the nose profile and piercing the billet.

### Two Forging Operations

Secured to the ram of the press, is a large casting which carries the swivel block containing the two punches. When the billet has been placed in position, the large diameter punch is swung to a central position and locked by the stop shown to the right of the press. The ram is now forced down, the pressure causing the hot metal at the bottom of the billet to take the shape of the forming die. The ram is raised and the piercing punch swung into position and locked as before. The punch is lubricated with a little graphite and oil, and a small quantity of coal dust is thrown on the top surface of the billet, after which the ram again descends, and the piercing punch is forced into the steel, the metal flowing up and around the punch. It sometimes requires two or more applications of water before the ram reaches its final position. The outside diameter of the rough shell is practically the same as the hot billet, which is about 1-16 smaller at the top end than the bore of the die.

The forging being completed, the punches are swung clear, the shell being removed by the air hoist and dropped to one side of the press, where it is gauged for length and wall thickness, being next removed to another department to

cool. It occasionally happens that a punch will seize while forging a shell. Provision is, therefore, made whereby a stripping block can be placed in a slide on the upper surface of the die to remove the shell from the punch as the ram ascends. However, even with all due precautions, this device may refuse to operate successfully, and it is then necessary to remove the punch, with the shell still on it, from the press. By carefully hammering and expanding the shell under a steam hammer, before it becomes too cold, the punch may be withdrawn; but it is often more profitable to scrap both the shell and the punch. Punches, under ordinary conditions, have a life of about 300 shells.

### CATALOGUES AND SAMPLES TO RUSSIA

THE best method for United Kingdom firms to adopt in sending catalogues and samples to Russia is by parcel post; they are of course submitted to the Russian censorship. Catalogues should be printed in Russian. The best method of distributing catalogues is through a local agent. No distinction is made in the customs duties to be paid whether catalogues or goods are sent by post or express. Samples should be as small as possible to avoid extra charge for freight and duty, as it frequently happens that valueless and useless samples pay heavy duties. The duty on unbound catalogues imported into Russia is levied at the rate of 18.70 roubles per pound (about 26 cents per pound). Bound or half-bound catalogues pay an additional duty of 1.65 roubles per pound, making the duty about 28 cents per pound.

### GERMAN TRADE PROMOTION IN CHINA

REVIEWING the methods used by the Germans in seeking trade expansions in China, the Assistant British Commercial Attache states that every effort is made by German firms to get into friendly relation with the Chinese, and to create a demand for their goods, not waiting for the demand to come to them, as British firms have often done. Specialization is not required at present, but quick decision, enterprise, and determination. The German technical bureaux are very successful. Groups of non-competing manufacturers in Germany send out a joint representative, with expert knowledge of the Chinese and their methods of business, and he does the work of advertising and suggesting. When orders are forthcoming they go direct to the manufacturers of the group, and thus openings are secured at a minimum of expense. Several British organizations

have attempted to follow on these lines, but they have generally failed through their schemes being too ambitious.

### FUTURE OF HYDRAULIC POWER

A REMARKABLE sequel to fuel shortage is being witnessed throughout the world. The press records the attention which, almost suddenly, is concentrated upon the utilization of water power and the prospective development of energy in that direction is used at times as a consolation for the long-prophesied diminution of British coal resources. It seems quite reasonable to assume that we are nearer the beginning than the end of our knowledge of utilising the world's three great prime movers—water, steam and internal combustion—and it seems certain that water power energy will in the future have a great bearing upon the question of fuel consumption.

All the civilised nations, also Germany, are devoting more and more attention to hydraulic power, and Italy in particular—spurred by the present enormous cost of coal—finds something worth attention in the calculation that there is enough water power in the peninsula to answer all industrial requirements. One feels certain that Britain's Dominions across the sea will continue to harness even more fully the magnificent water powers which exist in so many areas and develop their local resources on the most advanced engineering lines.

### TESTING AND MOUNTING GRINDING WHEELS.

TIGHTEN the flanges only enough to hold the wheel firmly, avoiding any unnecessary strain. The importance of this statement is emphasized by the fact that on a 1½ in. floor stand, equipped with 8 in. standard relieved flanges, a man with a 24 in. wrench can easily exert a crushing pressure between the wheel flanges of 3,600 pounds or over 1¾ tons.

Every grinding wheel should be protected with a hood—in fact, in many instances it is necessary to use a hood to comply with the laws for safety and dust removal. The hood should have some method of adjustment so that the top end may follow the wheel as it wears, thus giving ample protection for small wheels as well as large ones.

If grinding is done dry, the hood should be connected with a suitable dust removal system. After the wheel is in place, the hood should be adjusted to the size of wheel and the rest should be so adjusted that work cannot be caught between the rest and the wheel.

A Department for the Interchange and Distribution of Shop and Office Data  
and Ideas Evolved from Actual Practical Application and Experience

## DESIGN OF LATHE. PLANER, SHAPER, AND SLOTTER TOOLS—II.

**A**S stated in the closing paragraph of Part 1 of this series of articles on page 60, July 20 issue, the three elements of profile, clearance and rake must be taken into consideration when determining a set of standard tools. These features are therefore dealt with in the order named.

### Standard Profiles.

It is not often realized what an important bearing the profile of a tool has on its efficiency as a cutting instrument. Why do we first use a taper for threading a hole? Obviously, because we spread the cut over a greater length of cutting edge. In Fig. 2 is seen a representation of two tools performing the same work at the same depth of cut and at the same rate of feed.

The cross sectional area of the chip is the same in both cases, yet the one on the right is obviously a much thinner chip than the other. The cut being spread over a greater length of cutting edge, this tool will be therefore much more durable than the one on the left. On the other hand, if the tool on the left will stand up to the work imposed on the short length of cutting edge in action, it follows that, with the tool on the right, the rate of feed can be increased, until for an equal length of cutting edge the same cross sectional area of chip is being cut from the work. Suppose the length of cutting edge in the one case to be twice the length of the other, twice the amount of work can be done in the same time.

### Curved or Straight Cutting Edge

The first rule, then, in selecting a tool profile is that the maximum length

FIG. 2. DIAGRAM ILLUSTRATING THE EFFECT ON THE CHIP THICKNESS WHEN THE CUTTING EDGE IS LENGTHENED, WHILE THE DEPTH OF CUT AND RATE OF SPEED REMAIN THE SAME.

of cutting edge must be in action for any given depth of cut. Whether the portion of cutting edge in action should be straight or curved depends somewhat on circumstances. A straight-

edged tool is easier to make than a round-nosed tool and deserves consideration on that account. It also distributes the cut evenly over the cutting edge no matter what the depth of cut.

A round-nosed tool has a certain advantage in that it lends itself to a greater variety of operations without

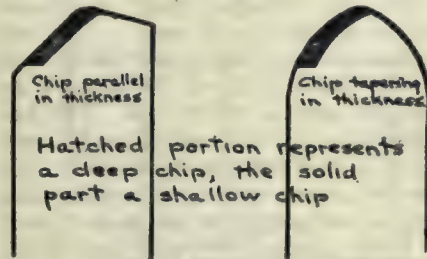

FIG. 3. DIAGRAM SHOWING DIFFERENCE IN THE CHIP SECTION CUT BY A STRAIGHT-EDGED AND A ROUND-NOSED TOOL

material alteration. Where the depth of cut is constantly varying, as in turning a hammered forging, the cut is distributed over the cutting edge in a varying amount more proportional to the strength of the tool nose. The choice between the two, therefore, is perhaps more one of preference than of efficiency.

### The Chip Feature

There is one side of the question, however, on which we have not touched, because we have no data other than intuition, on which to base our conclusions. A study of Figure 4 reveals the fact that the chip from a straight-edged tool consists of a band of metal with straight serrations across it, while that from a round-nosed tool has curved serrations across it.

### The Metal Being Cut

This would seem to point the moral that the metal in the chip is more distorted, therefore more power is consumed, when using a round-nosed tool than when using a straight-edged tool, for the following reasons.

Each portion of the width of the chip passes away from the cutting edge at right angles to a tangent at the point of cut. With a straight-edged tool the chip passes over the top face freely because the directions of motion of every portion of the chip are parallel to each other. With a round-nosed tool the extreme edges of the chip are, while passing across the cutting edge, running towards each other, therefore extra work is done in forcing the chip away from the cutting edge owing to the rubbing action that must take place between the

particles of metal forming each chip section.

The action can be likened to a column of soldiers in fours marching through a passage too narrow to accommodate them. The soldiers will find it much harder work marching while trying to squeeze through the passage than when stepping freely along the open road. It may therefore be assumed that in the main the preference would seem to lie with a tool having a straight cutting edge. Any advantage which the round-nosed tool may be considered to possess can easily be given to the straight-edged tool by grinding a large radius on the point.

So far we have assumed that the metal to be cut is homogeneous. That this is not so every lathe hand knows. Frequently the cut must be taken just under a hard skin, which very soon destroys that part of the cutting edge against which it bears. Again the surface of the work may be scaly or gritty, which is equally as bad for the tool.

These things must influence our choice of a suitable tool. It is logical to assume that the shorter the length of cutting-edge in contact with the skin, the less damage will be done to the tool and the easier it will be to repair what damage is done. The shortest distance through the skin is at right angles to the surface, therefore where the tool comes in contact with the skin, the cutting-edge should be as nearly as possible following that shortest distance.

This leads us to the statement of our second rule, which is that the least amount of cutting edge must come in contact with the skin of the work, if this is liable to damage the cutting-edge.

The third point to be considered is the

FIG. 4. TWO PIECES OF CHIP, BOTH MADE AT SAME DEPTH OF CUT AND RATE OF FEED. THE UPPER CHIP WAS MADE BY A ROUND-NOSED TOOL, THE OTHER BY A STRAIGHT-EDGED TOOL.

absorption of the heat generated by the cut. This heat can be dissipated very largely by means of a copious flow of lubricant, but this will not prevent damage to the point of the tool unless there

is a sufficiently large amount of metal in the tool nose to prevent the extreme point from becoming overheated. Any lubricant or coolant, as our American friends prefer to call it, which flows past the cut without touching either the tool or the work is wasted from a cooling point of view. Therefore the broader the tool nose the greater will

consider a specific case—let us say the turning of a forged shaft or spindle. How shall we select a tool for our purpose? Our decision will depend on several factors which may be stated thus:—

(1)—Hardness or otherwise of the material to be cut, and whether the work is annealed or not. These affect the rake as much as the profile of the tool, but must be taken into consideration in deciding on the rate of feed it is possible to adopt.

(2)—Whether the work has a hard skin or not. This has considerable influence on the choice of tool, as will be shown later.

(3)—The strength, rigidity and power of the machine to be used. This will govern the depth of cut and rate of feed.

(4)—The solidity of the support the tool will have in the tool-rest. The American type of single swivelling tool-post offers a poor support to the tool. The English pattern with four clamping bolts and no overhang gives plenty of support to the tool and allows a much heavier cut to be taken than any other type.

(5)—The frailty or otherwise of the work. If the work is liable to spring away from the tool, light cuts with a more or less pointed tool are necessary, otherwise the work will not be true and will be full of chatter-marks.

#### Assumed Combination of Foregoing Factors

Let us take as our first assumption the following combination of the above factors. The forging to be turned is 0.30 carbon steel, tough but annealed, therefore fairly easy to cut. The skin is clean and will not affect the tool very much. The machine to be used is one with plenty of power and strength, so that it will not be possible to overload it with the  $\frac{3}{8}$ -in. depth of cut and  $\frac{1}{8}$ -in. feed we intend to adopt, while the forging is also strong enough to take such a cut without spring. Our machine will carry a tool of  $1\frac{1}{4}$ -in. x  $1\frac{3}{4}$ -in. section.

FIG. 6. DIAGRAM SHOWING THE METHOD OF ARRIVING AT THE PROFILE OF A TOOL WHEN THE CONDITIONS ARE ALL KNOWN.

Rule 2 does not apply in this case, as the forging has been annealed and the skin hardness need not worry us. Rules 1 and 3 decree a long cutting edge and a mass of metal behind the cutting edge.

Draw two parallel lines  $\frac{3}{8}$ -in. apart to represent the depth of cut, and two

more parallel lines at right angles to these  $1\frac{1}{4}$ -in. apart to represent the width of tool, as shown in Fig. 6. Next draw the line AB, the intersection with the side of tool at A to come about  $\frac{1}{8}$ -in. outside the work, while the intersection with the top line at B should leave, say,  $\frac{1}{2}$ -in. of metal to the right to comply with Rule 3. The tool shape is then completed by drawing a radius of, say,  $\frac{1}{4}$ -in. at B, and a tangent to it at about 5 to 10 degrees so as to clear the work as the tool feeds along. We now have a tool profile, as indicated by the heavy

FIG. 7. A SUITABLE TOOL FOR ROUGH TURNING WHEN THE WORK HAS A HARD SKIN.

lines in Fig. 6. This tool profile gives a long cutting edge with an allowance for any small variation in depth of cut, while plenty of metal remains at the back of the cutting edge to absorb the heat. Such a tool is ideal for the class of work outlined. The angle which AB makes with the side of the tool—the side angle, see Fig. 1—is 55 degrees.

Now let us inquire into what changes, if any, are rendered necessary by variations in the five factors previously mentioned. Suppose the forging is unannealed and has a skin that is hard enough to quickly wear away the cutting edge. All three rules come into operation now, that is, in addition to the cutting edge being as long as possible, it must cut through the skin at, or nearly at, right angles to the surface of the work.

Turning to Fig. 6 again, this means that AB, instead of being drawn at 55 degrees to the side of the tool, must be very much steeper, even as steep as 5 degrees, while the long cutting edge is obtained by making the radius of the point very little less than the depth of cut. We now have a tool similar to that on the left of Fig. 7.

An alternative tool with exactly the same profile is shown on the right of Fig. 7. This tool, however, has been bent to give an overhung cutting edge, allowing all the metal indicated by the shaded portion to be ground away by resharpener, before the tool is unfit for further use without re-making.

#### Vibration Feature

Our next supposition will be that the machine is not over strong and vibration sets up under a  $\frac{3}{8}$ -in. cut and  $\frac{1}{8}$ -in. feed. Is it possible to maintain such a cut and feed by variation in the cutting tool used? The first point that arises is that the machine, unless there is some-

FIG. 5. TWO SIMILAR TOOLS, THAT ON THE LEFT BEING A VERY COMMONLY USED ROUGHING TOOL, AND THE ONE ON THE RIGHT BEING GROUND TO CONFORM TO RULE THREE.

be the chance that plenty of cooling fluid will fall on it. It is a mistake to consider that any metal not directly concerned with the cutting-edge, should be ground away. All non-essential metal that can be left on the tool nose should be left, as it assists materially in absorbing and dissipating the generated heat. The third rule, then, resolves itself into the following:—The maximum amount of metal must be left on the tool nose behind the cutting-edge to absorb the heat generated by the cut.

This rule is aptly illustrated in Fig. 5, which shows two precisely similar tools as far as the cutting angles are concerned. The one on the left is a very common tool for rough turning, and is to be found in many tool stores and lathe cupboards at the present time. If, however, such a tool is ground, as shown on the right—that is, with all possible metal left on the nose behind the cutting edge, the life of the tool will be greatly increased, while the actual turning will not be affected in the least. The three rules already discussed may be summarized as follows:—

(1)—Maximum length of cutting-edge in action.

(2)—Least amount of cutting-edge in contact with the skin.

(3)—Maximum amount of metal behind the cutting-edge.

They do not apply to every case without exception, but should be adopted in the selection of tool profiles wherever possible. The exceptions will not be numerous, only presenting themselves when the cut is out of the ordinary or the work is frail and liable to spring under the cut.

#### Factors in Tool Selection

To illustrate the application of these rules, it will not be out of place to con-

thing radically wrong with its design, must obviously be smaller than the one previously under consideration. It will, therefore, require a smaller tool section. Assuming this to be  $\frac{7}{8}$ -in.  $\times$   $1\frac{1}{4}$ -in., and following the method depicted in Fig. 6 for determining its shape, it is obvious that the side angle cannot be 55 degrees; it will be about 35 degrees, as shown in Fig. 8. It will be seen that with such a tool the cutting edge is not so long, and end thrust on the tool will not be so great.

It is possible, therefore, that the tool depicted in Fig. 8 will, on the weaker machine, take a  $\frac{3}{8}$ -in. cut at  $\frac{1}{4}$ -in. feed. If not, vibration can only be overcome by reducing the feed or the cutting speed, or both. It would not be policy to reduce the depth of cut, if it can be avoided.

This exhausts the variations in the combinations of factors previously named. It will be noted that all the tools developed to meet these variations are of the straight-edged variety. Exponents of the round nose will probably say we are at fault in this, that while admitting the straight-edged tool has some advantages, the round nose has more, especially when the work is excessively hard, as in turning shrapnel shell forgings. Our reply to this is, that the obvious advantages of the straight-edged tool are combined with all those

FIG. 8. A TOOL SIMILAR TO THAT DEVELOPED IN FIG. 6. BUT HAVING A SMALLER SECTION.

that the round nose can possess by grinding a radius on the point. The chip then tapers off to nothing at the point, while the thickest part of the chip is of even thickness and tends to curl away from the tool without absorbing more power than need be. The importance of selecting the right profile of tool for any particular operation can only be appreciated when it is realized that the right tool

(1)—Will cut at the highest possible surface speed.

(2)—Will need less re-grinding per amount of work done.

(3)—Will be more durable under all conditions.

(4)—Will help to materially increase the output.

(5)—Will, when ground with the correct rake, use up the minimum amount of power.

### Clearance

The subject of clearance on cutting tools has, in the past, received scant attention from tool users. Everyone knows that clearance is necessary, though if asked why, most of them would be at a loss to give their reasons. If asked how much clearance a tool should have, they give the airy reply, "Oh, so much," as if the matter were of no moment and

tedious of metals. To keep the tool up to its work there is a certain amount of pressure required. This is proved by running a tool back over a surface it has just machined without withdrawing it from its cutting position. This happens every day on automatic turning machines, turret lathes, and other machines with fixed tools, so everybody should be aware that a tool mark is left, signifying

FIG. 9. DIAGRAM SHOWING RELATION BETWEEN SIDE CLEARANCE ON A LATHE TOOL AND RATE OF FEED. THE TOOL SHOWN IN EACH CASE HAS SIX DEGREES OF CLEARANCE, WHICH IS AMPLE FOR MUCH MORE THAN THE HIGHEST FEED RATE ANY TOOL WOULD STAND.

did not warrant any time being wasted on it. Those, however, who have made a careful study of tools, as we are endeavoring to do in this article, realize that clearance is almost as important as profile or rake. Let us first of all ask ourselves these questions: "What is clearance for? Is it necessary? If so, how much clearance shall we adopt on different tools?"

### Purpose of Clearance

What is clearance for? To answer this, let us consider one or two concrete cases. Take a planing tool and imagine it at work; if it has no front clearance underneath the tool, it will start cutting on the end of the work, but as soon as the cut has got going, the tool will rub along the cut surface. We have never actually tried planing with a tool having no clearance, but we can easily imagine what will happen. Bits of chip get under the tool, terrific heat will be generated and the tool will be rendered useless in a very short time.

This seems simple and logical, but when we consider the action of a turning tool, there is a difference. The work being round, recedes from the cutting edge as soon as it passes it, therefore the tool action cannot be compared to that of a planing tool. Yet can it not? We are leaving out of reckoning the elas-

that during the cut the tool was sprung away from the work or vice versa.

The elasticity which allows this spring is tending all the time to force the tool back against the work. If the tool, therefore, has no front clearance, this tendency will (presuming, of course, that the cutting edge is in line with the centre of the work) soon destroy the cutting edge and render the tool useless.

Then there is the question of side clearance, or clearance on that part of the tool which faces in the direction of the feed. In a planing or shaping tool precisely the same principles govern both side clearance and front clearance. In a turning tool, if we stop the lathe in the middle of a cut and trace the ridge between the turned and unturned surfaces, we find that it follows the path of a screw thread. In one complete turn round the work it strikes a point some distance behind the cutting edge of the tool, as shown in Fig. 9. It is obvious then that clearance on

FIG. 10. SKETCHES SHOWING THE DIFFERENCE BETWEEN A TOOL GROUND WITH A CURVED TOP FACE AND ONE GROUND WITH A STRAIGHT TOP FACE.

the tool is necessary, otherwise the side of the tool will not only rub along the ridge formed by the cut, but will actually

prevent the tool from cutting at all. . .

Given then that clearance is not only desirable, but necessary, what amount of clearance shall we adopt as our standard? On this point there are many different opinions. A little thought, however, will enable anyone to realize that the old proverb, "A miss is as good as a mile," holds good here. In other words, as long as the parts of the tool which should clear, do clear, that is all that is necessary.

#### Transmission and Dissipation of Heat

As stated previously, it is desirable that as much metal as possible should be left in the tool nose to assist in the transmission and dissipation of the heat generated. Further, the more metal that is ground away underneath the cutting edge, the less support the edge will receive to enable it to resist the pressure of the cut. This leads us to the logical conclusion that clearance must be as small as possible.

Varying conditions would seem to indicate that under this rule, as stated, different clearances should be adopted for every different combination of factors. Can we fix on a standard angle of clearance for each kind of tool and still conform, within reasonable limits, to the rule stated? Will any such tool, ground to our standard clearance angle, adapt itself without alteration to all the circumstances it is likely to meet?

Perhaps the widest variation of circumstances will be differences of feed. In Fig. 9 is seen the diagrammatic representation of a 3-in. bar being turned at five different rates of feed. The tool angles are the same in each case. If then a tool can be found which will be equally suitable for the extravagant rate of a half-inch feed per revolution and the more ordinary rate of 0.100-in. per revolution, then, we think, the above question is satisfactorily answered. The tool shown in Fig. 9 has six degrees of side clearance, which is the standard clearance for the majority of the tools included in the Lumsden Chart. We recommend, however, that five degrees be adopted as the actual standard in the finished tool, the six degrees being ground on in the roughing before hardening. In the subsequent hand sharpening, it is then an easy matter to just touch up near the cutting edge, when the standard of five degrees or thereabouts is at once obtained.

There are many cases where even a smaller clearance than five degrees is desirable, especially in delicate tools, such as parting tools. A parting tool is an example of clearance being reduced to minimum. The sides of the tool nose taper from front to back one degree only each side, and from top to bottom only two degrees each side.

#### Rake

Watch a tool at work in any lathe or planer and trace the path of the chip as

it curls away from the cutting edge. A straight line drawn in the direction of that path from the cutting edge gives the rake of the top face of the tool. This applies whether the tool has a straight top face or a curved top face.

Now we venture to assert that there are as many different ideas on rake as there are men using cutting tools. One man likes a very keen rake; he takes the precaution of having two tools for each job, so that as soon as one is dulled he changes them and has the used one re-ground. Another prefers a smaller rake angle because his tool lasts so much longer. Still another prefers to use a tool with very little rake; chips come off in short curls all blue and violet, and it looks as if he were doing such a lot of work. The kind of tool for which a man shows preference is a fairly good criterion by which to judge his character.

Theoretically, the question of rake is extremely complicated. Practically, it resolves itself into a long series of compromises. It is intimately concerned with the nature of the metals being cut; thus, we require a different rake on a tool of any one profile for cutting hard and soft steels, cast iron, brass, bronze, copper, aluminum, etc. If we inquire, even in the briefest manner, into the theory of rake, we are confronted by a problem that could not be exhausted in many articles of this description, while in the end we should be no nearer the establishment of our set of standard tools than we were at the beginning. Let it suffice then to make a few statements on the subject, based on the experience of every tool user. Metals divide themselves naturally into a number of groups, summarized into those which are:—

#### Metal Groups

- (1)—Soft and tenacious, including very soft steels and copper.
- (2)—Tough, but fairly easy to cut, including the majority of low carbon steels and certain kinds of bronze.
- (3)—Very tough and difficult to cut, including carbon steels, tool steel and most alloy steels.
- (4)—Brittle, including ordinary unchilled cast iron and some grades of bronze.
- (5)—Very brittle, including most brasses and chilled cast iron.

Each one of these groups require a different rake—those in Class 1 a very keen rake; those in Class 5 little or no rake at all, while Classes 2 to 4 require varying degrees of rake in between the two extremes. The great majority of tools are required for Classes 2 and 4, therefore, if we can so frame our standards that they cover the requirements of these two classes, while, with very little alteration, they can be made suitable for the other classes, we have introduced the desirable quality of flexi-

bility into our standard set of tools, and we have reduced our standards to the smallest possible number of variations.

This matter will be gone into more fully when we come to the considerations of what shall be included in our standard set of tools. We pass next to a discussion on the relative merits of straight and curved top faces.

#### Curved Face Tools

When the Lumsden oscillating tool grinder was first offered for sale on the Continent of Europe, it was not fitted with any attachment by means of which tools with curved top faces could be produced. This type of tool was in such general use, managers and machine hands being united in insisting on its manifold advantages, that it became necessary to design an attachment which would enable such tools to be quickly and accurately produced. This attachment now forms part of the standard equipment of every machine, and we believe we are stating a fact when we say that it offers the only mechanical means in existence for grinding hollow-curved tool faces.

Are our continental neighbors ahead of us in this matter, or are they wrong in attaching such importance to the curved face? That the hollow-curved face has many advantages is being amply demonstrated in many British works, since the Lumsden attachment opened up an easy means of grinding tools with curved faces. What are these advantages? They may be stated in two sentences as follows:—

(1)—They cut easily with the absorption of less power than straight-faced tools require.

(2)—They permit the use of keen angles without weakening the tool nose.

Both these statements require proof, but the first cannot be proved on paper; it can only be demonstrated in the shop. It is a statement of fact, nevertheless, and anyone can easily verify it for himself by taking two tools of precisely similar profile, and grinding one with a straight top face at the maximum rake angle he thinks the tool and the work will allow. The other he should experiment with, first by grinding a shallow curve in the top face and trying that; then he can grind the curve a little deeper and a little deeper still, trying it each time until he finds the cutting edge is so keen that it will not stand up to the cut. The experimenter will be surprised at the results he can thus obtain and incidentally he will gain much useful knowledge of the properties of cutting tools.

The second reason can easily be demonstrated by a sketch. See Figure 10. The rake at the extreme edge on a curved face tool is equal to the angle made by a tangent to the curve at that point;

a tool, therefore, to have the same rake as the curved face tool shown on the left in Fig. 10 must be ground to the absurd shape indicated by the non-shaded portion. On the other hand two tools from which an approximately equal amount of metal has been removed are shown on the right hand in Fig. 10. Here the extra keenness of rake obtained by grinding the top face with a hollow curve instead of straight is clearly shown.

This leads us naturally to ask whether such a keen rake is desirable. We refer any such enquirer to the experiments mentioned above, for they will prove to him that wherever rake is desirable at all, a curved-face tool will give better results and more efficient cutting than a straight-faced tool. The curved face seems to lend itself to the curl of the chip, which comes away more freely and with less apparent effort than it does from a straight face.

That the curved face is more natural is also shown by examination of any straight-faced tool that has been used for taking heavy cuts in steel. If the tool has been used for a reasonable length of time and is still cutting well, it will be noticed that at the extreme edge a small portion of the steel being cut has fused itself on the tool, while immediately behind this the chip has carved for itself a curved face by wearing the metal of the tool away. Most, if not all, operators of heavy lathes know that a tool in that condition is better even than a new tool. Grinding tools with a curved top face is then merely an endeavour to impart to them the natural condition they would otherwise assume for themselves after a little use.

### Conclusions

In conclusion, we may state that after several years of experience devoted entirely to the manufacture and application of tools for use on hundreds of different machines under a very large variety of conditions, we have come to believe that wherever a curved face can be given to a tool, it makes for better all-round general use than is possible with a straight-faced tool. The amount of rake to adopt for all tools is so varied that it can only be considered in relation to each separate tool shape, and we have not yet reached that part of our subject. Its consideration will therefore be deferred till later.

### WORN LOOSE PULLEY REPAIR

By J. E. Simmons

THE writer has used the following method of repairing loose pulleys when the wear on both shaft and pulley has been excessive. When properly fitted the repaired parts are as good as new, while the cost and delay of providing a new

shaft are avoided, as in most cases the shaft is worn down and no great benefit can be obtained by simply reboring and bushing the pulley.

The upper sketch in the illustration shows the complete job. The worn part of the shaft is first turned down suf-

REPAIRING A WORN LOOSE PULLEY.

ficiently to clean up with a good surface over a length equal to the width of the pulley loss. The pulley is now bored out so as to allow space for a bushing of average thickness to fit between the pulley and the shaft. A piece of good sound bearing brass is bored out a running fit for the reduced part of shaft and turned a running fit in pulley, being then finished to length and split in halves with a hack saw. A number of small holes are now drilled in both halves for the purpose of holding lubricant.

In assembling, the tight pulley is mounted flush with the edge of the turned part of shaft, and the two halves of the bushing are then placed in position and the rebored loose pulley slipped over it, a shafting collar retaining all in position as shown.

### THE SCHEME OF THINGS

By F. H. Mayoh.

ALL progress and development are built around some centre of effort or enterprise, and in the realm of mechanical engineering the statement is specially evident. A gas engine is built about its piston; an automobile about its engine; a machine about the work it has to perform; a tool about the apparatus it serves to make; and industries—in the larger sense, about their product.

To-day, bullets are the centre around which much effort and energy are displayed. Guns are being built about bullets; chemicals are being manufactured for use with bullets, tools are being built for guns, industries are being built or revised for everything pertaining to bullets, and for some time, trade and technical journals have been devoting considerable space to the subject of bullets. This must, therefore, be the bullet age in mechanics. The word "bullet" is

used here in the broad sense, that is any projectile fired from a gun.

Primarily, a bullet has two distinctions, and therein lies its difference from most mechanical problems. It is a composition problem, it is a tool making problem from a rapid production point of view, it is a heat treatment problem and a projection problem, and as labor required for its manufacture is uncertain, incidentally its elimination where possible also becomes a problem.

If one were to investigate a number of machine shops throughout the country he would no doubt be surprised at the number of different methods in vogue for obtaining the same result. If one were to go into a large arsenal and suggest a manufacturing change along lines of something seen in one of these shops, he would probably be confronted with the remark, "It isn't arsenal practice." Thus we notice there is a huge difference between standard arsenal practice and the practice of necessity.

As a function, the make up of a bullet takes first consideration and mechanically it does not present very great difficulties. Ordinary rifle shots are drawn and the swedging work handled, with the greatest possible speed. The machines for producing them are full automatic, fool-proof, and in a large degree capable of being operated by girls. Shrapnel shell varies considerably in size, in composition and in method of handling. A good many separate operations are necessary; the parts must be well made and thoroughly gauged. Special machinery and tools are required throughout, embracing press tools, turning tools, thread millers, drilling machines, and graduating machines. Lastly a very high degree of interchangeability should be maintained so that all parts no matter where made, will go together on the field.

The second function is to maintain the outside bullet or shell dimensions. This must be done with full realization of where to work from, for in many cases it is not sufficient to caliper the outside but the lengths should be gauged relative to the outside, as for instance in gauging a shrapnel shell case the proper procedure would be to place the shell into a hole representing a gun barrel, push over a swinging latch which represents the breech block and thus having reproduced the conditions under which the shell will be fired the length of case must become evident. Likewise relative duties inside and outside of a shell must be borne in mind throughout the handling of shells or bullets.

It is impracticable to make guns with tool-makers. A gun is a highly developed instrument suited for rapid, interchangeable manufacture. All of a size should be bored alike to receive shells

made anywhere, rifled true, sighted exact and manufactured by machinery, not men. It is impracticable to make guns without a large preliminary expenditure, the tools should be first-class, that's the tool-maker's function, that is the reason there's such a large demand for tool-makers at the present moment.

The first requisite of a gun is the steel. It must be a good quality, and properly treated to withstand the shock. The tools for its manufacture should be the best, quick operating, easily repaired, plenty of them and worked to the limit of capacity. The operations on some parts are many and are often so light that hand-feeding of the machines is profitable. Light grinding or filing operations are often profitable, complete gauging systems are necessary, but above all it does not pay to stint in equipment. If you must study mechanics from a bullet, study the game with an open mind; production and accuracy are the essentials. Develop the best system time will permit don't hesitate to consult the ordnance experts, for their life has been spent studying just your problems, and though strangers to you they are the experts of the moment.

## TRANSMISSION SAFETY—II.

**D**UE to the high speed often attained by belts, it is necessary to make adequate provision for shifting them with safety. Approved mechanical belt-shifters should be provided in each case, in connection with tight-and-loose pulleys; and it is advisable to have these shifters equipped with rollers where they come in contact with the belts. This not only reduces the wear on the edges of the belts (which may be considerable in the course of a year), but also minimizes the chance of the ragged edge of a belt catching in the belt-shifter and causing damage. The belt-shifter should be provided with an approved automatic locking device, and the handle of the belt-shifter should be located so that the workman can operate it from his regular working position without inconvenience.

### Belt Shifting Methods and Devices

A very common risk is run in connection with the shifting of belts by allowing an unshipped belt to ride on the revolving shaft. Such a belt, especially when loosely joined by lacing, may gradually travel around until the joint reaches the shaft, then be drawn tight enough to engage the driven pulley, and thus suddenly start the machine. This is particularly true of small pulleys, and though this specific danger may appear to be remote, we could cite cases in

which it has led to serious consequences. For this reason, it is far better to hang the unshipped belt on a suitable book or belt-perch.

Although we strongly advocate the installation of mechanical belt-shifters for all machines, we are well aware that in many plants the shifting is still done by hand, or by the use of poles. Hand-shifting is too dangerous to be tolerated under circumstances, and the use of a pole or stick adds but little to the safety of the operation. A recent accident may be cited as an illustration of the danger. While an employe was shipping a belt by means of a stick, the stick slipped between the arms of a moving pulley and was forced back into the workman's side. Two of his ribs were broken, and internal injuries also resulted. This accident could not have occurred if tight-and-loose pulleys and a suitable mechanical belt-shifter had been installed previously. An even more dangerous procedure is that of removing or shifting belts with the feet. Employees who persist in this practice should be severely disciplined.

### Belt Dressing Application

The operation of applying dressing to belts to prevent them from slipping leads to many serious accidents. Care should be taken to apply the dressing at the point where the belt leaves the pulley, and to roll up the sleeves so that they will not catch upon belt fastenings or other parts of the belt. It is hardly feasible to stop the belt while the dressing is being applied, because it is then very hard to reach all parts of the belt, and to apply the dressing smoothly and uniformly. The safest and best way, without doubt, is to remove the belt altogether, when it needs dressing, and stretch it out along a bench or on a clean floor. It should then be thoroughly cleansed and repaired after which the new dressing may be applied and worked in. There are few shops, however, in which the superintendents are willing to have the work done in this way, because it involves a considerable expense for labor, and it will also be necessary, in many cases, to have extra belts on hand, to take the places of those that are being cleaned and dressed. Small belts can be handled in this way without any very heavy expense, and in such cases it is possible to do the work outside of the regular hours, so that it will not be necessary to provide extra belts. It is not feasible, however, to remove large, heavy belts and treat them in this way, on account of the great labor involved.

### Running Belt Treatment Precautions

If a belt must be dressed while it is running, the work should be assigned

to a man who is known to be intelligent and cautious, because in such cases the problem of accident prevention is probably at least 75 per cent. a human problem. In other words, it will depend mainly upon the man himself, whether he is injured or not. Liquid dressing should first be warmed so that it will flow freely, and it should then be applied by a brush and never by the use of rags or cotton waste, because either of these is likely to catch on belt fastenings or rough places in the edges of the belt, and be drawn against the belt along with the man's hand. Experts often recommend that the engine (or motor) driving the belt be slowed down while the dressing is applied. This is a wise precaution, where it can be done satisfactorily.

In dressing a moving belt, the dressing, as previously stated, should be applied to the belt near the point where the belt leaves the pulley. Sometimes this is not practicable on account of local conditions, and in such cases extraordinary care should be taken.

### Typical Example

We recall a case, says the Travellers' Standard, in which a belt two feet wide, running over a six-foot pulley, had to be dressed under such conditions that the only part of the belt that was accessible was the part that was within two feet of the pulley, on the in-running side. Moreover, the belt could be approached only on one side, so that the man who applied the dressing had to reach over to the further side of the belt from where he stood. To guard against accident he was in the habit of removing his jumper and rolling his right shirtsleeve up into a tight roll as near as possible to his shoulder, working with his right arm bare.

When conditions of this kind have to be met, a stout railing should be provided for the protection of the man, and it should be placed so that he can lean upon it if necessary, and so that he can catch at it and thus save himself, in case he should lose his balance. When a man is engaged in any perilous operation, of this kind, care should be taken to prevent his being startled by any unusual sound or other disturbing cause. Nobody having ragged or loose-fitting clothing should be allowed near a rapidly-moving belt at any time, either to apply dressing to it or for any other purpose.

**Steamers Released.**—The British Admiralty has released three of the White Star-Dominion Line steamers which were formerly in the Canadian trade—the Northland, Southland and Canada.

# Series of Practical Questions and Answers for Mechanics

*Every care is being taken to include only pertinent practical questions, and give same direct, reliable answers. Catch questions will be avoided. Arithmetic, consisting of simple addition, subtraction, multiplication and division will be found a useful companion study.*

**Question.**—We desire to change the volume of a flue to twice its present capacity. It is now 8 inches in diameter, and requires to be changed to one of oblong cross-section, the width being 8 inches. What must be the length?

**Answer.**—The area of the 8-inch diameter pipe will be  $8 \times 8 \times .7854$ , or 50.2656 square inches. Twice this will be 100.53 square inches. As this will be the area of the oblong flue required, the length will be the area divided by the width, or 100.53 divided by 8 equals 12.57 inches.

**Question.**—We have a groove to cut in the face of a cast iron block; the base is square and the sides are perpendicular to the base, while the top face makes an angle of 30 degrees with the base (on the ends), the front and back being parallelograms. The sides of the groove are to be square with the base and the bottom parallel with the top face, with the direction of groove inclined at an angle of 60 degrees with the front or back face. What must be the angle of inclination for the head when cutting the groove?

**Answer.**—What we gather from the data given is, that the groove is to be shaped on the top surface of the block,

tical, and in position C the head is inclined 30 degrees, the inclination for position B would be  $90 : 30 = : x$ , or  $x = 30 \times 30$

$\frac{30}{30} = 10$  degrees.

90

**Question.**—What is meant by "casting out the nines" when proving work in multiplication?

**Answer.**—This is the process frequently adopted in checking work in arithmetic, and very often is a sure means in tracing mistakes; for instance, suppose we are multiplying 638529 by .7854, we proceed as follows:—

638529	33	9)33(3—6
.7854	24	9)24(2—6
2554116		9)36(4—0
3192645		
5108232		
4469703		
5015006766	36	9)36(4—0

After multiplying the two numbers together and obtaining the product, add together the digits in the multiplicand, the multiplier and the product. In this example, the sum of the digits in the

mainder should be other than a cipher, a similar remainder should be shown in the product.

**Question.**—How is it that a body weighs less when submerged in water than when suspended in the air?

**Answer.**—If the specific gravity of the body is less than that of the liquid in which it is placed, the body will be only partly submerged, the displaced water being equal to the total weight of the floating body. When the specific gravity is greater than the water, it will be necessary to exert a force (as shown by the upper arrow) to keep the body from sinking to the bottom. Now, it is quite clear that the pressure of the water upon the sides of the block shown in the sketch will equalize each other, but the pressure on the bottom tending to lift the body will be greater, due to the larger head. The pressure acting downwards will be  $12 \times 12 \times 18 \times .03617 = 93.75$  lbs., and the pressure acting upwards is  $12 \times 12 \times 30 \times .03617 = 156.25$  lbs. Then the difference in this case will be the weight of the water displaced, or 156.25 minus 93.75 equals 62.5 lbs., which is the approximate weight of a cubic foot of water.

**Question.**—When making castings by the die-casting process, what is the method adopted to determine the soundness of the various parts of the metal?

**Answer.**—The general process of determining the soundness of small castings is to select a few of the first pieces made and break them up until one is found that is entirely free from blow-holes or other defects. When one is secured that is reasonably perfect, it is used as a basis for calculations and all subsequent castings must balance this test piece. By this method the smallest blow-hole or variation in weight is easily detected.

as shown at B. The elevations A, B and C illustrate the position of the block when held in the vise. With the groove running from the front to the back and parallel with the ends, the head would be in a vertical position. With groove running from end to end and parallel with front or back, the head would be inclined at an angle of 30 degrees, to keep the sides perpendicular to the base. By swinging the shaper vise around 30 degrees, to bring the block in the desired position, the angle of inclination would be reduced in proportion. Therefore, when in position A the head is ver-

multiplicand is 33; dividing this by 9 we get 3 and 6 over. The sum of the digits in the multiplier is 24; dividing this by 9 we get 2 and 6 over. By multiplying these two remainders together and again dividing by 9 we get 4 and 0 over. This last remainder should be the same as that obtained by following the same process with the product. Thus, the sum of the digits in the product is 36, and this divided by 9 gives 4 and 0 over, so the work can be considered as correct. If, after multiplying the remainders in the multiplicand and the multiplier and dividing by 9, the re-

**Question.**—In the operation of a block and tackle, having a combination of pulleys, the weight is raised one foot while the free end passes through six feet. What force would be required to raise a weight of 350 pounds?

**Answer.**—From the above question it is seen that there are six ropes supporting the weight, therefore, the weight and the force applied will be in the same ratio as the supporting ropes and the free end, or 6 to 1. Then the power required to raise 350 pounds will be 350 divided by 6, or  $58\frac{1}{2}$  pounds.

**Question.**—A milling machine hand had a number of lathe square centres to shape up, so that the cutting angle would be 60 degrees. The question which puzzled him was the angle through which to tilt the head so that the included

angle at the corners would be 60 degrees. What would this angle be, and how is it obtained?

**Answer.**—A solution to this problem was given in a former issue of Canadian Machinery, but to make it more clear we will again explain. As the angle of two opposite edges will represent the original angle of the conic centre or 60 degrees, it is clear that the angle of two opposite sides must be somewhat less. As shown in the sketch, the angle desired is C X O; the dotted portion being the original outline of the 60 degree conic centre. Suppose the diameter of the centre (a — b) is 2 inches, then to find the length (o — c) use the formula,

Side opposite = hypotenuse  $\times$  sine =  $1 \times$  sine of 45 degrees, or  $1 \times .70711 = .70711$  inches.

The length (x — o) will be the vertical height of an equilateral triangle, whose side is 2 inches, or by formula,

Side opposite = hypotenuse  $\times$  sine =  $2 \times .86603 = 1.73206$  inches.

Then angle C X O can be found from the formula,

$$\text{Tangent} = \frac{\text{side opposite } .70711}{\text{side adjacent } 1.73206} =$$

.40824.

Angle corresponding equals 22 degrees, 12  $\frac{1}{2}$  minutes.

## SURFACE GRINDING

By H. W. Dunbar.

THERE is a fact relating to surface grinding which I do not believe is thoroughly understood, at least this is

my observation, since the question "Why do you not have variable speed regulation on the work table of your surface grinding machine?" has been asked me so many times. The answer is very simple: "Because we do not need it," which will be understood by the following explanation:

In cylindrical grinding, a given size of machine has to handle a great variety of different classes and different kinds of work, which naturally introduces as many different diameters. With a given grade of wheel, in order to keep the surface speed of the work constant so that this wheel will have practically the same cutting action on all these different diameters, it becomes necessary to introduce a speed change device between the source of power which revolves the work and the latter itself.

This usually takes the form of gearing or belting, and a considerable range is provided to maintain an equally constant surface speed of work, from the smallest it is practicable to grind in such a machine to the largest that the machine will accommodate. Also one other factor enters, but will be disregarded at this time and touched on a bit later, that is, the different arcs of contact in the diameter of the wheel or the diameter of the work.

### No Change In Diameter.

Now in surface grinding this is different. There is no change in diameter; when you change work on the table of the machine the diameter has been stretched out in a long straight line. What corresponds to the periphery of the cylindrical piece of work being ground is now a flat surface resting upon the table of the machine, and no matter whether your piece is short or long, wide or narrow, the rate of speed with which it travels underneath the wheel is always constant. So that after the proper wheel speed has been determined, also the proper table speed, which gives you the correct relative work speed to wheel speed under average conditions, there is never any further need for change in the speed of the table which carries the work on a surface grinding machine.

The same is true of the wheel speed, this need not be changed either, since the design of the wheel sleeve is such that but a certain amount of wheel can be worn from the diameter, then it becomes useless. This amount, of course, is sufficient to make the wheel an economical proposition, even more so than by the practice of utilizing the greater amount of actual cubic inches of the wheel, and changing the speed at different intervals when the wheel action

changes, there being a wide enough range in the possibility of a given grain and grade of wheel to be cared for by the single speed specified.

### Arc of Contact of Wheel

One other fact that must be borne in mind when operating a surface grinding machine for surface work, and one which influences in a degree the selection of the wheel for a maximum amount of work, is the arc of contact which the wheel has with the work being ground. In the surface grinding operation there is considerably more wheel buried in the work during actual cutting time than with the same diameter wheel on a cylindrical piece of work. So that for surface grinding it is usually safe to say that very much softer wheels must be selected, and wheels that are somewhat coarser, since we must provide room for chips being removed while the particles of wheel are buried in the steel. The same principle, of course, applies to cylindrical work where the work gets larger and larger in diameter, as in this class of work the wheel is also buried deeper in the part being ground than on smaller diameters, and therefore, will require a somewhat softer and coarser wheel. From "Little Known Facts About Grinding" in "Grits and Grinds."

## FALL OF OVERHEAD SHAFTING

A HAZARD that must be considered in workshops is that due to the fall of overhead shafting. This sort of accident is somewhat rare, because the danger is so obvious that even the most careless managers usually take precautions against it; but when a section of shafting weighing tons and running the length of the building does fall, enormous damage is likely to be caused. To much care cannot be exercised in making sure that the supports for line shafting are substantial, and that they are securely fastened. A weak or insecure hanger imposes an extra burden on the other hangers, and the shaft is ultimately thrown out of alignment. It then moves with an eccentric motion, which gradually becomes more pronounced as the other hangers are affected by it and work loose. The belt becomes tighter during one part of a revolution of the shafting than during the remaining part, and finally a time will come when a heavy load is applied at the moment when the belt is abnormally tight, and then the whole line of shafting may be pulled down with disastrous results to life and material.

# Burning Blast Furnace Gas Under Boilers and Stoves\*

By A. N. Diehl\*\*

*Being a discussion of ways and means whereby greater efficiency will be procurable from the use of the blast furnace gas in hot blast stoves and boilers. It is claimed that a saving of 12.3 cents per ton of iron can be made by increasing the boiler efficiency from 55 to 65 per cent. in burning that portion of the blast furnace gas not utilized in the hot blast stoves.*

ABOUT 48 to 50 per cent. of the thermal value of the fuel used in the blast furnace passes from the top in the form of sensible and latent heat in the gas. Of this about 30 per cent. is used in the hot blast stove, 10 per cent. is lost, and 60 per cent. is used in the boilers and engines. The possibility of raising the boiler efficiency from 55 to 65 per cent. in burning the blast furnace gas has, the writer argues, been almost overlooked.

The average blast furnace gas on lake ores has approximately the following analysis by volume: CO<sub>2</sub>, 12.5 per cent.; CO, 25.4 per cent.; H<sub>2</sub>, 3.5 per cent.; nitrogen, 58.4 per cent. This gas will have a thermal value at 62 deg. Fah. and 30 in. barometer of 92 B.t.u., and contain from 30 to 35 gr. of water per cubic foot. It also contains considerable dust, which, however, can be removed by washing, the dust content being lowered from 3 gr. to approximately 0.2 gr. a cubic foot, the moisture at the same time being lowered from 30 gr. to 8 to 10 gr. per cubic foot. While washing the gas reduces its temperature 220 deg., this is counterbalanced by the gain due to the cleanliness of the heating surfaces with the washed gas and by the reduction of moisture. Equally high flame temperatures can be obtained from either clean or dirty gas. The temperatures being in the neighborhood of 2,030 deg.

## Burner Performance

The performance of a burner may be determined by the observation of flame temperature, and by analysis of the products of combustion. The temperature observation cannot be used as an absolute standard of burner efficiency, and a method based on the analysis of the products of combustion must be used. A burner is put at 100 per cent. efficiency when the analysis of the products of combustion shows only carbon dioxide and nitrogen. It is suggested that the products of combustion be analyzed at a point about 2 ft. from the point of ignition. The 100 per cent. efficient burner is defined as follows: "A gas burner is operated at 100 per cent. combustion efficiency when the analysis of a sample, drawn from a point 2 ft. beyond the point of ignition, shows perfect combustion."

Under this definition the boiler effi-

ciency does not enter into the problem, and burners may be compared with one another. The efficiency of burners varies with the load upon them, and it is desirable to develop a burner that will closely approach perfection at boiler loads of 75 to 200 per cent. of the boiler rated horse-power. The essential condition for this is a maximum flame temperature obtained by a perfect mixture of air and gas in the burner. The burners here discussed cannot be compared, however, on the basis of burner efficiency on account

closer the complete combustion is to the burner, the better heating exchange is possible. It is best to add both gas and air at only one point—through the burner, and control them there. Gas and air have channeling tendencies when entered separately. Forced draft will facilitate flame intensity, and it acts in such a manner as to make combustion of more gas possible in the stove than under atmospheric conditions. If the stove is sufficiently large, considerable advantage can be derived by this method. It is ad-

of insufficient data. Blast furnace gas burners may be classified under six general types, and are described below.

## Stove Application

The following points should be observed in using blast furnace gas in burners in connection with stoves: Clean gas should be used when possible. Large heating surfaces should be exposed as an aid in lowering stack temperatures. Equal draft and blast distribution over the entire checker area is essential to good practice. All gas should be consumed in the combustion chamber. The

visible to make daily flue gas analyses and have a technical supervision of the combustion.

(1)—Rectangular or circular nozzle burner with air added around it or by separate doors or both. An example of this type is the Spearman & Kennedy burner, Fig. 1. Air enters the stove through the clearance space around the burners and through doors in other parts of the stove circumference. Gas and air mix in the combustion chamber.

(2)—Rectangular or circular burner with air conducted into the gas jet by

\*From a paper before the American Iron and Steel Institute.

\*\*Asst. Supt. Duquesne Steel Works.

means of pipe or other opening. The Landgrebe burner, Fig. 2, is of this type. Air is admitted at the back of the gas tubes, and at the ends of them meets the gas, at which point mixing takes place. A separate gas valve is placed in the pipe connection to the gas main, and suitable slides, etc., are provided for regulating admission of air into the air chamber of the burner.

(3)—Burners which sub-divide air and gas into a series of streams, but do not mix in the burners. A burner of this type, developed at the Edgar Thompson Works of the Carnegie Steel Co., consists of two concentric passages—the inner one for gas and the outer one for air. The gas and air passages contain helically twisted vanes, the twists in the two helices being in opposite directions. The vanes run the full length of the respective barrels and serve to facilitate the mixture of the gas and air as they emerge from the burner. Another example of this class of burner is the Boynton burner, in use at the Lorain works of the National Tube Co. It is illustrated in Fig. 3. Air and gas are admitted in horizontal layers, this stratification being produced with the idea of obtaining an intimate mixture of air and gas at the point of admission.

(4)—A burner in which air is aspirated by means of an air jet at high pressure, as in a steam jet blower, the air

(5)—Burner through which all of the required air is forced and completely mixed with the gas before the ignition point. Fig. 5 illustrates a burner of this type in use on the stoves of the Wisconsin Steel Co., South Chicago. Another

FIG. 15. 500 H.P. B. & W. BOILER AT NATIONAL TUBE CO. PLANT, MCKEESPORT, PA., SHOWING 72% EFFICIENCY WITH OLD STYLE BURNER.

form of the same type is used at the American Steel & Wire Co. Central furnaces, Cleveland. The burner used at the latter is illustrated in Fig. 6. Air is supplied by a 16-in. turbo-blower, which runs at a constant speed, and, therefore, furnishes the required volume of air at a given rate. A gasometer-controlled damper placed in the gas downtake insures a correspondingly constant gas volume.

(6)—Burners to which air and gas are supplied after being perfectly mixed in

time in blast furnace plants range from 250 to 500 horse-power. They are usually equipped with feed-water heaters, but seldom with superheaters or economizers. Settings and baffles as a rule are in bad condition, and the efficiency of the average blast-furnace boiler plant could probably be increased from 5 to 10 per cent. by repair and constant upkeep of settings and baffles. The burner in general use comprises a pipe introduced into the combustion space under the boiler. The gas enters into a solid rectangle or circle, and the air in a thin layer around it. Air and gas are mixed in the combustion chamber and in the boiler flue space generally, the bulk of the work being done in the latter

### Controlling Gas Pressure and Quantity

The only method of controlling gas pressure and quantity is a butterfly valve placed in the supply line to the boilers. This method of control is used in order to insure the required pressure at all times at the gas cleaning plant, which is necessary so that the constant quantity of gas required by the stoves and the gas engines shall always be maintained. The variation in quantity and pressure of gas must be taken by the boilers. Pressure regulation at the boilers cannot be considered, and an amount of air proportional to the quantity of gas available must be supplied. This can be done in most equipments by means of damper regulation, in combination with sufficient air openings around the burners. Automatic damper regulation, controlled by pressure in the gas box between the butterfly valve and the burner, will probably give the best results.

### Raw Gas Feature

When raw gas is used, the boiler tubes should be blown regularly. Under constant conditions, stack temperatures have shown decreases of from 50 to 100 deg. Fahr. before and after blowing. On account of the loss due to excessive air leakage through the open doors, while the tubes are being blown, the economical period of blowing is every 12 hr. After the 12-hr. interval the deposits accumulate rapidly, causing a correspondingly rapid rise in the stack temperature.

Three general types of burners are in use in connection with boilers as follows:—(1)—Rectangular or circular nozzles, with air added around them or by separate air doors, or by a combination of both. (2)—Rectangular or circular burners with air conducted into the gas jet by means of pipes or other openings, and by means of auxiliary

Blast-Furnace Gas Burners Applied to Steam Boilers

from both sources mixing with the gas in the burner. The Freyn gas burner is of this type, and is illustrated in Fig. 4. These burners have been used on stoves of the Illinois Steel Co., South Chicago.

a fan, which draws in air on one side and gas on the other, discharging the mixture into a common outlet. This type is at present in process of development. Boilers in operation at the present

doors through which additional air is admitted around the burner nose. (3)—Rectangular or circular burners with all the air required for combustion conducted into the gas jet by means of pipes or other openings. Type 1 is known as the common burner.

### Distribution of Boiler Losses

The maximum average efficiency of a blast furnace boiler plant, using common burners and operating without the aid of technical supervision, is about 50 per cent., frequently being lower. An approximate distribution of the losses is about as follows:

Sensible heat in waste gases .36 per cent.  
CO in waste gases ..... 9 per cent.  
Radiation . . . . .5 per cent.

The distribution of the loss will, however, vary greatly with the load, the gas

through openings in the back of the air nozzle, being aspirated by the force of the gas blowing through the burner. The primary air supply is insufficient, and a secondary supply is drawn in by furnace draft through the secondary openings around the nose of the burner.

A series of tests was made by C. J. Bacon on Stirling, Rust and Wheeler boilers to compare Birkholz burner with those of so-called simple construction. The tests were of short duration and the evaporation was measured by steam flow meters instead of by weighing the feed water. The results showed in part that it is extremely difficult to make reliable adjustments of burners when judging solely by the appearance of the flame. The best combustion is accompanied by slightly smoky appearance of the flame, as seen through the glass observation windows of the Birkholz burner, rather than by the bluish-white color usually supposed to indicate perfect combustion. Special tests demonstrated that the as-

ers of the Rust and Stirling types as with boilers of the single-pass arrangement such as the Cahall and Wheeler.

### Special Burners of Type 2

Fig. 9 shows a burner developed at the Ohio Works of the Carnegie Steel Co. A series of tests on two 400-h.p. Stirling boilers fired with mixed raw and washed blast furnace gas indicated that the efficiency of this type of burner was about equal to that of the Birkholz burner. The McWilliams burner, shown in Fig. 10, is built on about the same principle as the burner shown in Fig. 9. The combustion is no better than in the common type of burner. Experiments showed that the draft, due to aspirating effect, increases with the gas quantity, but not in direct proportion to it. In a series of six 8-hr. tests with this burner on a 250-h.p. Babcock & Wilcox boiler, an efficiency of 49.7 per cent. was found to be about the average operating efficiency. Efficiencies ranging from 53.5 per cent.

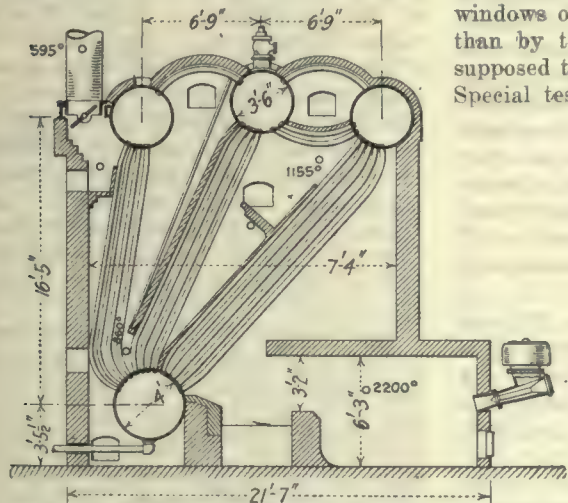

FIG. 16. GAS BURNER INSTALLATION IN 500 H.P. STIRLING BOILER, AT PITTSBURGH STEEL CO. PLANT, MONESSEN, PA.

FIG. 17. POSITIVE AIR SUPPLY BURNER AT DUQUESNE WORKS.

pressure, and the position of the stack damper.

The maximum efficiency occurs with neither a minimum sensible heat loss nor minimum CO loss, which is generally the case with high efficiency. The efficiency of 59.4 per cent. may be considered about the maximum under present conditions and equipment. It indicates that with attention to details of operation, a continuous operating efficiency of about 58 per cent. is possible at a rate of driving of 175 per cent. of rated boiler horsepower. While this is a low figure, it is probably exceeded by but few blast boiler plants. High efficiencies are possible, however, with old style burners, provided they are used in connection with large boilers, long combustion chambers, excellent conditions of setting and baffles, sufficient air supply and air regulation, together with close attention to performance.

### Birkholz-Terbeck Burner

A representative form of a burner of the second class is the Birkholz-Terbeck burner, shown in Fig. 7. In this burner the primary air supply is admitted

pirating effect of a Birkholz burner with three adjustable air inlets could not be depended upon to supply the proper amount of air for combustion under varying conditions of gas supply and stack draft.

Manual adjustment by experienced attendants is necessary to accomplish lasting improvement. While the mechanical devices of the Birkholz burner facilitate such adjustment, it will not give uniformly good results if unattended. The usual efficiency of boiler plants over long periods does not exceed 55 per cent., while the tests prove that 60 to 65 per cent. efficiency is easily obtainable if close attention is given to the physical upkeep of the boiler plant, even without additional expenditure for special types of burners. As high as 70 per cent. efficiency may be obtained from ordinary types of boilers equipped with the better class of burners, when given expert attention under favorable operating conditions. The degree of improvement in performance accompanying the use of improved burners of the Birkholz type evidently will not be so great with boil-

to 55 per cent. were obtained under the test conditions with the doors fastened tightly and all openings in the setting mudded up, additional air being admitted by moving back the screen around the burners.

### Burners of Type 3

An aspirating burner of Type 3, made at Duquesne for experimental purposes, is shown in Fig. 11. It consists of a series of air vanes at the top and bottom of the burner, the gas jet being contracted at each vane, but each contracted area being made larger than the preceding one. When operated at the rated capacity of the boiler, 250 h.p., a burner efficiency of 92 per cent. was obtained, but, on increasing the capacity, the efficiency dropped rapidly, due to unconsumed CO. In tests with this burner on a 250-h.p. Babcock & Wilcox boiler, a boiler efficiency of 63.7 per cent. was obtained. Tests made at the same time on an adjoining boiler using the common type of burner showed a boiler efficiency in the neighborhood of 56 per cent.

The Bradshaw burner shown in Fig.

12 is supposed to follow the principle of the Venturi meter. It consists of a rectangular casting through which the gas passes, air being admitted through narrow openings top and bottom for the full width of the burner. The casting is contracted at this point, and the reduction in pressure due to the increase in velocity provides the medium for air aspiration. The casting then flares out to permit expansion from the throat of the burner into the furnace. In tests on a 500-h.p. Stirling boiler (Fig. 16) at the works of the Pittsburgh Steel Co., Monessen, Pa., the boiler efficiency over the usual working range of gas pressure averaged 65.1 per cent. The test results showed, with an increase of gas above the amount for which the original adjustments of the burner were made, a loss of 8.2 per cent. due to unconsumed CO gases, proving that air in proportion was not induced through the burner.

Two modifications of the Bradshaw burner have been made, known as Fraser burners No. 1 and No. 2. The principal difference between these modifications and the Bradshaw burner lies in taking air to the contracted portion of the gas jet inside instead of outside. In burner No. 1 the side gas passages past the air box were made too small, resulting in only a small amount of gas passing under the air box. Burner No. 2 was designed to provide ample passage for gas on the sides of the air box, which resulted in more nearly equal gas pressures at the top and bottom of the burners. The test of Fraser burner No. 2 showed an average efficiency of 65.4 per cent.

Another burner of the general type of Class 3 is the Kling-Weidlein burner, developed at the Ohio works of the Carnegie Steel Company and illustrated in Fig. 14. The gas leaves the primary nozzle at high speed and in two streams, drawing the primary air in between the gas streams. The air mixes with the inside layers of the gas streams on their way to the ignition chamber, but before the latter is reached the secondary air is brought in in two streams and mixes with the outside layers of the gas stream. The results of tests with this burner showed that within small limits of pressure variations, a burner will aspirate practically, though not exactly, the correct quantities of air. For large pressure differences, however, regulation of gas pressure or air supply would be necessary to the maintenance of maximum efficiency.

#### Burners With Positive Air Supply

A burner of the type in which all the air is forced into the burner and completely mixed with the gas before the ignition point is shown in Fig. 17. All the air required for combustion is supplied by a motor-driven fan. Air enters the rectangular box at the back of the

burner, and after passing through the short pipes, mixes with the gas. Gas and air are thoroughly intermingled before reaching the point of ignition at the end of the burner. By careful regulation a burner efficiency of 96 per cent. was obtained. In a working arrangement of forced draft, the speed of the motor or engine driving the fan should be controlled by the gas pressure. Results of a representative test for this burner on a 250-h.p. Babcock & Wilcox boiler showed 21.9 per cent. of CO<sub>2</sub> in the stack gases, and 3.1 per cent. O<sub>2</sub>, while CO was zero. The boiler efficiency in this test was 65.6 per cent.

#### Conclusions Regarding Boiler Practice

The most noticeable feature in the comparison of boiler tests with relation to the burners is that in the same plant nearly all of the burners compared showed very little difference in efficiency, although there may be considerable difference between particular tests in the same plant. The plant must, therefore, be considered a constant, and we must conclude that the equipment and supervision is superior in the plant showing the best results. The following general conclusions were drawn as a result of all the tests of burners in connection with boilers:

(1)—Under test conditions all types of burners appear to approximate equal results with the same equipment and management, although engineering features in some types render manipulation and control easier.

(2)—High efficiencies will prevail when the equipment is properly designed and in first-class condition.

(3)—Combustion chambers should be sufficiently large to accomplish full combustion of the gas before it passes the first row of boiler tubes. Combustion chambers should be proportioned to suit the burner conditions. In general, the size of combustion chambers should be inversely proportional to the degree of mixing in the burner.

(4)—Balanced draft control in the combustion chamber and necessary damper regulation with consequent exclusion of infiltrated air is a decided advantage.

(5)—Although a burner can be designed to aspirate the proper quantity of air at one pressure, none has yet been designed to aspirate over any very considerable range of varying gas pressures. Over small ranges a number of the recently developed burners approach within practical limits the condition of sufficient air supply.

(6)—Gas pressures constantly varying within relatively wide limits render impossible the attainment of good combustion without constant regulation of the air supply.

(7)—Unless preheaters, superheaters

or economizers are used, claims of boiler efficiencies of over 70 per cent. should be accepted with caution.

(8)—Constant gas analysis coupled with intelligent supervision is one of the principal factors in obtaining continuous high efficiency and control without much change in equipment.

(9)—A properly designed burner with easy means of controlling air and gas mixtures is far preferable to slipshod methods which prevail in many plants.—Data courtesy The Iron Age.

#### NICKEL REFINERY TO BE BUILT

THE manufacture of nickel in Canada is to begin immediately, that is to say, as soon as the necessary arrangements can be completed and the necessary plant provided. The work will be done by the International Nickel Co., at whose refining plant in New Jersey most of the nickel from Ontario mines is now being manufactured. The International Nickel Co., has already given instructions for the incorporation of a Canadian Company. This information while not coming officially, is from an authentic source and the statement is made that no time is to be lost in giving effect to the arrangements now being made.

The question of the establishment of a Canadian plant by this corporation was taken up by the Government with the management of the International Nickel Co. some months ago and a return was tabled in Parliament containing the company's promise to erect in Canada a plant of sufficient size to provide all the nickel required by Great Britain. It was intimated by the company at that time that the Canadian plant should be erected somewhere along or near the Atlantic seaboard, apparently with a view to simplifying matters relating to the shipment of certain materials used in the treatment of the ore.

These considerations do not seem to have carried the same weight, as representatives of the company, after examining a number of sites in the Maritime Provinces have since been actively engaged in looking over a number of sites in Ontario, with a view to establishing the refinery near to the point of ore production. There is no information available as to whether a final selection of a site has been made, but the expectation is that the plant will be located in Ontario.

Edward Fitzgerald, of Montreal, former purchasing agent of the C. P. R., has been officially named as assistant to the chairman of the Imperial Munitions Board.

## HEAT TREATMENT OF DROP FORGINGS

By W. C. Peterson.

**T**HE manufacture of drop forgings involves mechanical treatment, consisting of forming the metal under a hammer, or in a forging machine, and heat treatment, which modifies the structure of the steel. The handling of the material, in the course of this treatment, has a great influence on the physical properties of the finished forging.

### Temperature Feature

All steels have a certain temperature or range of temperatures, at which the structure of the steel undergoes a change. This range of temperatures is called the critical range. Upon heating a piece of steel from atmospheric temperature up through the critical range and then allowing it to cool very slowly down to its original temperature, the steel appears as a very close crystalline structure. Upon further heating of the steel through its critical range, it is found, just upon emerging from this range, to have a very fine grained structure. Allowing it to cool from this temperature it is found that a very slight crystallization takes place, after which practically no change in the structure is noticeable.

In drop-forging it is necessary to have the temperature well above the critical range, since otherwise the metal would not be plastic enough to forge. As the forging is being heated beyond the critical range the grain size increases, until, at the temperature at which forging begins, a very coarse crystalline structure is apparent. Application of heavy blows or of pressure soon breaks up this large grain, particularly if this hammering or pressing is continued sufficiently.

### Getting Best Results

To get the best results in drop-forging the hammering should continue, for it must be remembered that large and crystalline grains will result if the steel be allowed to cool undisturbed, especially if the temperature is well above the critical range. This can easily be demonstrated by heating a piece of steel up to the proper forging temperature and hitting it just a few blows with the hammer and then allowing it to cool undisturbed. It shows a remarkable grain growth. On the other hand, if the steel upon heating to the proper temperature is hammered continuously to a point

where the temperature is just above the critical range, it will be found to have a very finely grained structure. It is well, then, to designate a finishing temperature on forged work, and the nearer this temperature is to the critical, and yet above it, the better the forgings will be.

### Effect of Cold Working

If the hot working of the metal is to continue to a temperature below the critical range, the structure will still be fine grained, since crystallization ceases at the beginning of this range, yet it would be distorted. Distortion in the structure of steel means decreased ductility and in some cases even brittleness. Such a condition actually exists in the cold working of steel, since it is known that the structure existing below the critical range has no tendency to crystallize. The effect of cold working is essentially to distort, by stretching the elements of the structure in the direction of the force applied, causing decreased ductility and brittleness. Instances of the decrease in ductility are noted in the cold working of steel where it is necessary to anneal before completing the final operation, such as in tube or wire drawing.

Although it may be possible to keep the finishing temperature as near the critical range as is practicable, it is found that the inner portions of a forging of small cross section have a much coarser grain than those of the outside. It is extremely difficult to prevent this, for if the finishing temperature is correct for the outside, the inner portions are hotter, causing grain growth, and again if it were possible to adopt the proper temperature for the inside portion of a forging, the outside would be affected by cold working, causing strains, etc.

### Heat Treatment Features

In practice, then, conditions exist which are not ideal for forging, such as uniformity in finishing temperatures, and difference in structure from centre to outside. Heat treatment is destined to overcome to a marked degree the influences of these irregularities. It consists principally in heating the forgings to the proper temperature and holding this temperature constant until the entire forging is uniformly heated through, finally cooling to atmospheric temperature.

In heating up the forging, the temperature should be carried through the critical range, for in so doing any coarse

structure which might have been present before is now destroyed, and the entire forging at this temperature presents an almost homogeneous structure. If the temperature remains below the critical range no change in structure takes place, and, of course, the purpose of heat treatment is defeated. There is danger also of heating too far above the critical range, since the steel when just out of the critical possesses the finest grain size, and upon further heating these grains grow large and coarse.

The distance the temperature should be carried beyond the critical is largely dependent upon the size of the forging. A forging of small cross section should be quenched perhaps immediately upon the completion of the transformation, while a large forging, on the other hand, should be heated to a slightly higher temperature. This demand is made largely on account of the relative rapidity with which a small forging cools as compared to a large one.

### Cooling Regulation

In cooling from the heating temperature, such mediums as air, oil, water and brine are employed. Air cools much slower than water, and water slower than brine. It is very desirable to employ different rates of cooling because it is then possible to regulate the physical properties in the forgings. For example, if a forging is to be employed in such a way as to give ease in machining it would be cooled very slowly and perhaps in the same furnace in which it was heated. This would be done, of course, at the sacrifice of strength. Again, if it were desired that the forging possess strength and a certain amount of rigidity and hardness, it would be cooled more quickly, perhaps in oil or even water.

### Selection of Cooling Mediums

The selection of cooling mediums in the heat treatment of forgings depends upon the constituents of the steel. With straight carbon steels, the lower the carbon content the more rapidly the metal will cool. In this class of steels where the carbon is below 0.15, water may be used. This would increase the strength and yet not impair the elongation. If a steel of higher carbon content is quenched in water, the elongation will be very low, necessitating a second or drawing heat. This reheating is absolutely necessary when two forgings of different size and of medium carbon content are to be quenched, if the same physical properties are to be retained.

With forgings made of high carbon alloy steel there is danger of cracking in water. On some forgings where the adjoining cross sections abruptly vary in size, even when oil is used as a quench, the second or drawing heat must be carried out almost immediately after the quenching heat. This is due to the great difference in the rate of cooling of the various cross sections, resulting in strains which eventually produce cracks. In forgings of this character it has been found very beneficial to first anneal the material so as to facilitate the machining operations which remove as much metal as is possible, leaving only enough for light cuts. Where possible, only sufficient stock for grinding should be left. This would no doubt leave the forging in many cases with more uniform cross sections, making a more uniform heat-treatment possible.

This method has been instrumental in increasing the strength of important automobile forgings at least 30 per cent. The advantage has not ended here, for the cost of tools and their upkeep has been considerably reduced on account of the ductility of the forging in its rough state when treated in this manner.—From a paper presented at the meeting of the American Drop Forge Association in Philadelphia last month. The author is associated with the Packard Motor Car Co., Detroit, Mich.

## SPELTER, ITS GRADES AND USES

By G. C. Stone.

**S**PELTER, like all commercial metals contains impurities, but, unlike most other metals, none of these impurities are advantageous for any of the purposes for which it is used. The effects of these impurities on different products made from it vary greatly, hence the necessity for several grades differing in purity. Spelter is used for the following purposes, in quantities in the order mentioned:—Galvanizing, alloys, rolling, ornamental castings and miscellaneous uses.

For ordinary galvanizing, the effect of the common impurities is not very great. Iron is objectionable as causing a loss in dross and in making the coating more brittle and liable to crack and peel off. Lead, up to the limit found in commercial spelter, has no serious effect, but is objectionable when present in large quantity, as it liquidates in the bath and does not enter the coating and is, therefore, wasted. Lead is usually worth less than zinc and the purchaser does not wish to pay for it at zinc prices. The four higher grades of spelter are chiefly used for alloys and the specifications were principally made for the alloy makers and do not, in all cases,

call for metal suitable for some of the other purposes for which it is used.

### Aluminum

In alloys, aluminum is frequently very injurious, 0.01 per cent. in many cases making brass useless for the purposes for which it is intended. In the few instances where its presence is desired, it is more satisfactory to add it directly than as a constituent of the spelter. The specifications (as proposed for the American Society for Testing Materials in 1915), therefore, require that the four higher grades of spelter shall be entirely free from aluminum.

### Iron

Iron is always present in spelter, but is very undesirable in brass and similar alloys, making them harder and greatly increasing the hardness due to cold working. The increased hardness is very objectionable, causing a greater consumption of power and endangering the rolling mills and drawing presses.

### Lead

Lead is very objectionable in some alloys and essential in others, and the main variation in the different grades of spelter is in the allowable amount of lead. High-grade spelter, which is used for alloys that are to be subjected to the most severe spinning and drawing operations, can be rejected if it contains over 0.07 per cent. of lead, as lead reduces the ductility of brass. Intermediate spelter, with a lead limit of 0.20 per cent. is used for alloys that do not have to undergo as severe treatment, and also very largely for alloys like manganese bronze that are used both cast and wrought.

Brass special has a lead limit of 0.60 per cent., and is mainly used for brasses where the maximum ductility is not required. The lead and iron are limited to 0.69 per cent. and 0.03 per cent. respectively, because brass made from such spelter is used for ordinary drawing, spinning and forming work where the requirements are not especially severe.

Selected spelter, carrying the maximum 0.80 per cent. of lead, and 0.04 per cent. iron, is used by brass manufacturers for making alloys to which lead is added in order to secure free cutting qualities. Material of this kind is usually made into rods and heavy sheets for the manufacturing of small articles by turning, milling and drilling operations. Such brass must contain sufficient lead to reduce the strength of the material and cause the chips to break easily.

Owing to the fact that brass is usually made in crucibles in small quantities, uniformity in the spelter is of the greatest importance. As lead segregates

badly, and more markedly the higher the proportion, the lead limit of the average sample is made low enough to allow for this tendency without injurious effect on the product. Even when the brass manufacturer adds lead, he does so in known amounts and thus obtains a uniform alloy from the different pots, which would not be possible if all the lead needed were contained in the spelter.

### Cadmium

There is very little doubt that cadmium in zinc is very injurious for some of the purposes for which it is used, as it renders it harder and much more brittle. There is, however, considerable difference of opinion as to how far these undesirable properties persist in alloys made from zinc containing cadmium. The majority of brass-makers are of opinion that the higher temperature of the brass pots cause so much of the cadmium to volatilize that the residual amount has very little deleterious effect.

There is no doubt that large amounts of cadmium, say 1 or 2 per cent., make brass hard and brittle. We have no reliable information at present showing the effect of small amounts of cadmium on the alloys, and the evidence on this point is extremely conflicting. Cadmium, together with lead, seems to intensify the effect of the latter and also causes the brass to become more sensitive to the effect of overheating in the various annealing operations to which the wrought material is subjected.

Very little spelter is made containing as much cadmium as is alloyed for intermediate and brass special, and the specifications, therefore, put practically no limit on cadmium except for high grade. Whatever the facts may be for alloys, it is certain that the amounts of cadmium allowed by the specifications are much greater than are permissible for other purposes for which zinc is used. The question of cadmium in the better grade is complicated by the fact that until the last year and a half practically all the high-grade and most of the intermediate spelter was made by one company from ores that are free from cadmium. The alloy makers have, therefore, had no extended experience with the effect of cadmium in the better grades of spelter, and during the last eighteen months conditions have been so abnormal that it is difficult to draw conclusions.

### High Grade Spelter Uses

High-grade spelter is very extensively used for galvanizing telegraph and telephone wires which are required to stand sharp bending when making the "line-man's splice;" as it has been found that if impure spelter is used, the coating cracks and peels off the joint. The only

high-grade spelter that has been used for this purpose is entirely free from cadmium. Cadmium being the element most likely to cause this trouble, it is very doubtful whether metal containing as much as is allowed by the specifications (0.05 per cent.) would be suitable for this purpose.

For rolling, cadmium causes such severe cracking that metal containing much of it is not economical; but as practically all the zinc rolling mills produce their own spelter, this matter is within their own control and the specifications do not affect them.

For ornamental castings no spelter described by the specifications would be satisfactory. The high-grade is all right as far as lead and iron are concerned, but with the maximum cadmium allowed, it would be impossible to make castings of many of the common shapes.

The foregoing was submitted as an addendum to the report of the Committee on Non-Ferrous Metals and Alloys at the meeting of the American Society for Testing Materials, Atlantic City, N.J. The author is metallurgist to the New Jersey Tire Co.

## GAS WORKS AND HIGH EXPLOSIVES

IN the presidential address before the Institution of Gas Engineers (England), it was stated that to-day we are largely dependent on our gas engineers for supplies of high explosives. The extraction of benzol and toluol from gas has been a problem that has engrossed the attention of every gas engineer. For obvious reasons the merits or demerits of particular systems, and methods adopted, were not discussed at any length. It was, however, indicated that the output of benzol and toluol had become more and more satisfactory, and was such as to encourage further effort toward even greater achievement.

### Pre-War Benzol and Toluol

In pre-war times the production of benzol and toluol had not presented itself as a commercial proposition to the average gas engineer. The quantity produced per ton of coal carbonized under ordinary working conditions and the comparatively low prices obtainable were not of sufficient importance to attract attention. Occasionally it would be pointed out that if the whole of the benzol were washed out of the gas produced in the United Kingdom, the resultant quantity would be a considerable national asset, but the adherence of our legislators to an illuminating power standard precluded the possibility of any serious attempts being made to recover this valuable coal gas constituent.

Necessity knows no law, and the munition needs of the country has enabled

the gas consumer to discover that an illuminating power standard is not a necessity, and that if he obtains gas of a sufficiently high calorific value he is quite as well served for all practical purposes as he was under the old conditions. If we can also show that the supply of a debenzolised gas will eventually enable us to supply gas at a lower cost, he will be more than reconciled to the change. I think it very probable that legislation abolishing the illuminating power standard will be one of the results of our present experiences.

### Benzol After the War

The question arises, will the debenzolising of gas pay after the war is over? I most certainly think it will. About thirty years ago several installations of carbonizing plants were erected in colliery districts for the purpose of carbonizing cheap slack for the residual products only. These were in operation successfully for some years; but eventually prices of residuals fell, and the process was abandoned. It would be natural to say, Will not the same thing happen again? I think not. Our conditions are totally different.

In the case of the carbonizing works, most of the gas produced was used for fuel in the carbonizing plant; the rest was wasted. The coke produced was necessarily of an inferior quality, and was almost unsaleable. In our case, however, gas and coke are the principal means of revenue, and any enhancement of the value of other residuals is a clear gain. The process used by the carbonizing plant was quite simple. The gas produced was cooled, washed in heavy oil (creosote or green oil), purified from ammonia, and burnt in the retort-settings and under the steam boilers; the surplus gas, as I said before, being wasted. The heavy oil was distilled for benzol and toluol, and returned to the washers. The washers which were found most effective were of a modified Livesey type, and two or more were usually run in series.

### Coal Tar Colors

Before the war most of us believed that we were conducting our business on the most economical and sound lines. Every care was exercised to prevent waste at every point of the process; and the price obtainable for residuals warranted us in supposing that supplies were just about equal to the demand. The war, however, has rudely shaken many of our preconceived ideas. It is not only in our business (i.e., the gas making business) that an awakening has taken place. Look, for example, to the great dye industry. Though the discovery of the manufacture of dyes and colors from coal tar extracts was made in Britain, the manufacture of them had

become monopolized by the enemy, and practically the whole of the coal tar products we produced were being shipped abroad. Having regard to the close connection there is between the manufacture of artificial dyes and of high explosives—the fundamental raw materials being the same in each case—it is not too much to say that every dye manufactory in Germany could be, and probably was, converted into a manufactory of high explosives in a remarkably short period of time. It was also a serious thought for us that we had not only lost our grip on a wealth-producing industry, but allowed the country to be denuded of this means of defence.

An interesting speech was made by Milton Sharp at a recent meeting of the Bradford Dyers' Association. After pointing out the relationship that exists between the production of aniline dyes and the future protection of the country due to an enlarged capacity for the production of high explosives, he asked whether all the work that had been done, the money spent, and the plants erected for the production and working up of these raw materials were to be sacrificed when hostilities ended. I do not think they will be. The general trend of thought in the country to-day is to hold on to what we have got and to reach out further for extensions in trade in all directions.

Recently, in the House of Commons, Mr. Chamberlain gave a very clear intimation of the attitude which this Government has found itself constrained by the logic of facts to adopt. He declared that all sections would agree that, after the experience of this war we could not leave the work of reconstruction of our trade to chance, and could not maintain a policy of complete laissez faire free from Government interference or assistance. If such a new and constructive spirit is to guide the deliberations of our statesmen on the economic safeguarding of the trade of the Empire, we can rest assured that the demand for home produced benzol and toluol will be permanent.

### Gas or Benzol First?

Will the debenzolising of gas pay after the war is over, and which will give the best financial results—a high benzol yield with some loss in the volume of gas produced, or the sacrifice of residual product returns by straining after the highest possible yield of gas? These are questions to which no definite answer can meantime be given, the future of residual products being in the "lap of the gods." If it should be found, as it may, that the production of benzol bears strongly on that of gas, then considerable research will be demanded relative to carbonization conditions.

Analyses of gasworks tars in the Counties of York, Durham, and North-

umberland indicate that the best benzol and toluol results are attained where horizontal retorts are in use, the coal being carbonized in thin layers and at a medium temperature. In this connection it is interesting to note that the carbonizing works of thirty years ago found the adoption of inclined retorts to considerably reduce their benzol yield. An investigation into the conditions of carbonizing best suited for the economical production of both gas and benzol may be one of the results of the war.

### CONSTANT SPEED, VARIABLE VOLUME AIR COMPRESSOR

IN order to operate the extensive equipment at the Hollinger Gold Mines, there has recently been installed at their plant at Timmins, Ont., a large Fraser & Chalmers constant speed, variable volume air compressor. This machine, shown in the accompanying illustrations is direct connected to an 800 b.h.p. synchronous motor, three-phase, 25-cycles, 12,000 volts, having a speed of 125 revolutions per minute. The rotor is made in two halves, mounted on the crank shaft, and so designed as to give the necessary fly-wheel effect; the total weight of the rotor being approximately 17,000 pounds. Crank shaft is of steel, 20 inches in diameter, 17 feet long and weighs about 16,000 pounds. Main bearings are fitted with four-part boxes of cast iron, and babbitted. Sides and bottom boxes are made adjustable by means of wedges and screws, for taking up wear.

Cylinders are made of hard cold blast iron, barrels being cast with a liner to form a water jacket space around the cylinder. The high pressure cylinder has a diameter of 22½ inches, the low

INSTALLATION PLAN OF LARGE CONSTANT SPEED, VARIABLE VOLUME AIR COMPRESSOR.

pressure cylinder a diameter of 38 inches, the uniform stroke being 30 inches. Four removable covers are located in the outer casing, for cleaning out dirt or other foreign matter that might settle in the water jacket. Cylinder heads or valve chambers are cast separate and bolted to the barrels, each head being fitted with suction and delivery valves of the Hoerbiger-Rogler patent frictionless guide type. The suction and delivery valves are made of forged steel, as light as possible consistent with strength, and are designed to automatically open and close without assistance.

Front heads are connected direct to the guides, and have stuffing boxes and

glands complete, with Tripps metallic packing. The cylinders themselves are fitted with patent poppet unloading valves at each end, and are operated by eccentrics from a lay shaft on the high and low pressure side, driven by bevel gears off the crank shaft. The throw of these eccentrics, and the lift of the valves, are controlled by air governors (one on each cylinder), to regulate the amount of air to be delivered. Covers are arranged on each head to provide easy access to the valves and seats. Special valves are located in the discharge pipes, for opening to the atmosphere on starting up, and so reduce the starting torque to a minimum.

Air coolers, specially designed to suit local conditions, are installed in the basement. They are of the vertical type, arranged so that the tubes can be lifted out in one nest for cleaning purposes, without delay in operation. They consist of mild steel shells with cast iron covers. The interior cooling tubes are of brass, expanded and secured in muntz metal tube plates. Cold water passes through the tubes, the air across same being directed by means of baffle plates.

Forced lubrication is employed in the oiling system being supplied from a rotary pump. A tank is also installed to give a constant head of 15 feet on the bearings, in case anything goes wrong with the oil pump. When oil pressure falls below 5 lbs., it automatically feeds from the tank, at the same time ringing an alarm. A separate mechanically operated oil pump is used to lubricate the cylinders when under the air pressure.

The capacity of this machine is 4,500 cubic feet of free air per minute at 1,100 feet altitude, same being compressed to a pressure of 105 lbs. per sq. in. gauge.

ENGINE ROOM SHOWING AIR COMPRESSOR IN FOREGROUND

# PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

## BEYER BAROMETRIC CONDENSER

**T**HE Ingersoll-Rand Co., New York City, is placing on the market complete steam condensing plants for every service condition. This equipment includes the Beyer barometric condenser, for which the company has secured the patent rights, Imperial duplex and Ingersoll-Rogler straight line, reciprocating, dry vacuum pumps, and, where required, Cameron simplex and centrifugal pumps.

INSTALLATION OF BEYER BAROMETRIC CONDENSER.

The Beyer barometric condenser is of the counter-current type, in which air and cooling water flow in opposite directions. The steam inlet is at the bottom of the condensing vessel, the water inlet above, and the air removal opening at the top. The sheets of cooling water overflowing the pool at the inlet point meet the entering steam. The two are brought into intimate contact by conical baffle plates assisting the water to absorb to its full capacity the latent heat of the steam. The non-condensable air liberated by the condensing action rises through the falling water to the removal point at the top, being cooled to practically the temperature of the incoming

water. It is also to be noted that ample opportunity is given for the removal of the air content of the water before it mixes with the steam. This the manufacturers point out not only facilitates the mixing process, but permits the removal of air and vapor at a comparatively low temperature, a distinct advantage, as the reduced volume saves in vacuum pumpage horse-power.

The steam inlet is of large diameter to secure low velocity, and is hooded in such a way as to discharge the steam into the centre of the condensing vessel. The air removal opening is also of ample area, and is protected by a self-draining baffle and trap. This, it is said, positively prevents water being carried over into the vacuum pump. The hot waste water is discharged through the self-draining tail pipe, this pipe straddling the hot well and rigidly supporting the condenser.

The Imperial and Ingersoll-Rogler vacuum pumps are of standard type. They are high-speed reciprocating machines, wholly enclosed, automatically lubricated, and are claimed to economize floor space. When a water pump is required to elevate cooling water to the condenser head, Cameron pumps are provided, these being either reciprocating or centrifugal as desired. Where the level of the cold well is of sufficient height above the hot well, the condenser will lift its own cooling water, dispensing entirely with a water pump.

With this equipment it is claimed that the vacuum and water pumps, being independently operated, can be regulated to suit varying water temperatures and conditions, that in addition to efficiency in general service, such a plant is well adapted for duty as a central condensing unit serving a number of prime movers.

## FORCED LUBRICATION FOR STARTING MOTOR GENERATOR SETS

EXCEPTIONALLY large motor generator sets and other similar machines can be started with comparative ease if the

MOTOR GENERATOR STARTING ARRANGEMENT.

bearings are first flooded with oil. Writing in the General Electric Review on "Some Recent Developments in Central Station and Sub-station Equipment," J. R. Werth describes a special oiling system for the four bearings of a very large motor generator set, operating as

SECTION OF BEYER BAROMETRIC CONDENSER.

a frequency changer. Prior to the installation of that oiling system, the large starting motor had to exert an enormous torque to "break" the shaft from its bearings, especially after the set had been shut down for some hours.

The difficulty has been overcome by the installation of a special oiling system shown in the accompanying illustration. A small  $\frac{3}{4}$  horse-power motor driven pumping set forces oil between the shaft

and the bearings of the frequency-changing set, thus floating the shaft on a film of oil. It is now possible to start the set without any special starting motor, thereby saving valuable floor space and eliminating the continuous loss of energy involved in keeping the starting motor revolving twenty-four hours a day. After the set has been started sufficient lubrication is provided by the usual oil rings.

It will be gathered from the illustration that there is one pump for each pair of bearings, and that both pumps are driven by the single  $\frac{3}{4}$  horse-power motor. The holes in the bearings shown at A are for water-cooling connections. Relief valves are shown at B, equalizing pipes at C, pressure pipes at D, feed pipes to pumps at E, check valves at F, control valves at G, insulating couplings at H, and pressure gauges at K.

### INTERESTING DROP FORGING PLANT

AN extensive line of chains and forgings is manufactured by James McKay Co., Pittsburgh, who have specialized in this line for many years. Chains of every description are produced at their works from various grades of material

including such special irons as may be required to pass the most exacting tests. An interesting item of their plant

purposes. Car and locomotive forgings and a general line of commercial drop forgings render the output of the es-

SELF-OPENING DIE WITH BALL LATCH AND PROTECTING PLATE FOR SCREWS.

equipment is a 680,000-pound Olsen testing machine which is 30,000 pounds higher capacity than the next machine of its type. Both this machine and a smaller one of 100,000 pounds capacity are licensed by Lloyds Register, Bureau Veritas and kindred controlling bodies, an item of interest to Canadian users of chain for railroad, mechanical, or marine

establishment of interest to manufacturers, several examples of the product in this line being shown in the accompanying illustration.

### IMPROVED SELF-OPENING DIE

THE accompanying illustration shows the Model T Wells Self-Opening Die made by the Greenfield Tap & Die Corporation, Greenfield Mass., several changes affecting the general appearance and utility of this device having recently been made.

This model is especially designed for operations where the die revolves, the old style of projecting face trip having been discontinued, a neat and serviceable ball-shaped latch now opening the die when the cut is finished. A light steel shell is now provided for the purpose of covering the openings for chaser set screws which were formerly exposed, these preventing the entrance of fine chips and the resultant trouble. This shell can be instantly turned so as to expose the screws when it is desired to remove the chasers. In all other respects the die retains its essential points of construction.

### AUTOMATIC DUPLEX SLOT MILLING MACHINE

THE accompanying illustration shows a simple full automatic machine which it is claimed, gives satisfactory results in reduced costs and increased production. It is only necessary to place the piece in position and the machine will complete the work on it without any further attention, ceasing to cut when the price is completed.

The machine is capable of milling slots from  $\frac{1}{4}$  in. to 4 in. long, and  $\frac{1}{4}$  in. to  $1\frac{1}{2}$  in. wide clear through work up to 4 in. diameter or 2 in. on a side in steel or other material. The range of

VARIETY OF DROP FORGED PRODUCTS

work includes drift slots in spindle, tool post slots, elongated holes, keyways, slots in castings, tools, etc., mortice cuts, open fork ends, cuts in both ends of a piece to be in line, all of which can be machined accurately and rapidly without skilled attention. When working from both sides at once, the work is done in one-half the usual time or two separate pieces may be handled simultaneously without effort on the part of the operator.

By means of a cam and adjustable lever, the table carrying the work is moved back and forth, the length of travel being quickly adjusted. Changes of speed in the table travel are obtained through a cone pulley and change gears.

The spindle heads are designed for high speed work, the spindles being tapered at both ends, running in solid

SAMPLES OF CUTTINGS FROM HOLE TAPPED WITH GUN TAP.

Two-prong fish tail cutters are used, and adjustable fixtures to hold round work can be provided when desired.

The machine is built by the Garvin Machine Co., New York, and is supplied complete with steel oil pan, tank, strainer, pump, etc., all gearing being protected, and all working parts readily accessible.

#### TAP WITH NOVEL FEATURES

A NEW style of tap known as the gun tap has been developed, and is now being placed on the market by the Greenfield Tap & Die Corporation, Greenfield, Mass. This tap possesses certain features which vary from the regular style of tap, principal of which is the manner in which the cutting edges at the point are ground at an angle to

the axis of the tap, which enables the tap to cut with a shearing motion, the angle deflecting the chips so that they curl out ahead of the tap and do not clog up the flutes. On account of this action, therefore, these taps do not have to be backed out frequently on deep holes.

The cutting edges are formed with a

decided hook forward which causes the tap to work freely and make clean sharp threads. The remainder of the threaded portion of the tap acts as a lead screw, without any cutting action of its own, holding the work true to pitch. By using only two or three flutes to the tap, instead of four, and making them shallower than usual, much greater solidity is imparted to the body of the tap, rendering breakages comparatively rare.

The gun tap is ground on the angular cutting edge instead of in the flutes, re-grinding being possible till only two or three full threads are left. It gets its name from the fact that it was originally designed for use in gun work, where the exceedingly tough and wiring material in use was very apt to cause breakage of ordinary taps. This tap has also proven of great value where a hole penetrates two or more different kinds of material, tapping holes of this description without any trouble due to the change from one material to the other.

One type of transmission apparatus that should certainly be closely guarded is the chain drive. The hazard of this drive is about the same as that of gearing. Most chains are installed in a horizontal or nearly horizontal position, so that both sprockets are within reach of the workman. He is then in danger of having his hands or clothing caught between the chain and the sprockets. It is essential, for proper safeguarding, that both the chains and the sprockets be completely inclosed.

DUPLEX SLOT MILLING MACHINE.

bronze boxes, and having adjustment for taking up wear. A hardened step bearing is provided for receiving the thrust.

Each head may be adjusted independently along the bed to suit different lengths and conditions of cutters, the headstocks being also moved in and out simultaneously by hand wheel to any distance without interfering with the setting of the machine. Feeding takes place at each end of the stroke, the feed by ratchet and pawl being adjustable and arranged to automatically lift out and stop feeding when the required depth of cut is reached. In milling a through slot, provision is made to automatically back away one head when the slot is almost through, so that the other head can continue to advance and complete the slot, leaving no partition or fin at the bottom of the cut.

Work can be set on the table at any angle to produce a taper end of slot.

GUN TAP WITH ANGULAR CUTTING EDGES GIVING SHEARING MOTION TO CUT.

### BLACKLISTING NEUTRALS

**P**ATRIOTIC impulses of Canadian citizens have been stirred in some measure by the recent action of the Imperial Government in forbidding British subjects from dealing with American firms that have been black-listed for suspected trading with Germany. That such action would be ultimately taken has been more or less expected in certain quarters, and while the restriction, so far, applies to subjects resident in the United Kingdom, the probability of the various Dominions following suit should not be overlooked. In the event of the latter development taking place, the effects of such restriction will be felt in this country to a greater extent than in almost any other part of the Empire.

The official attitude of the United States Government is indicated in advices from Washington to the effect that while the programme of resentment to be adopted has not been fully outlined, it is understood that the preliminary action of the State Department will be a protest, based on the ground that the blacklist is a violation of moral right, and not to be tolerated, etc., the actual legality of the action being reserved for discussion later. That the matter will have serious results for the parties affected is fully realized by the United States State Department which contends that the blacklist amounts to a world-wide boycott.

This latter admission throws light on the whole aspect of the present situation and incidentally brings home to us the realization that having stood by our guns in actual battle, we may be compelled to do the same, metaphorically speaking, in the commercial battle which seems destined to follow on the heels of hostilities. In the absence of full details regarding the terms of the proclamation, it is not possible to estimate the full effect of such a measure should it be instituted in this country, but the fact that it might disturb hitherto friendly relations with firms across the line, is all the more reason why Canadian manufacturers dealing with firms who might be liable to proscription, should consider ways and means now whereby any resultant dislocation of business would be minimized if not altogether avoided.

A recent communication from the Swiss correspondent of an English contemporary contains several interesting statements regarding the future attitude of the Central Powers toward the trade of the British Empire. The importance of the engineering industry and the preparations being made by the Teutons for the utilization of that in-

dustry to its fullest extent during the period of recovery are hinted at.... "Scarcely any German or Austrian technical journals are now allowed to enter Switzerland or other neutral country, despite their being severely censored before going to press. Needless to say, no publications are more strictly watched than those dealing with engineering.... The Austrians and Germans as a rule believe or pretend to believe that the war will be followed by a period of immensely enhanced prosperity, when there will be a far greater demand for, than supply of labor, and when production in every department of commercial life will be proceeding with the utmost speed." Finally, the pertinent statement is made. "A trade war against the United Kingdom and British Dominions generally is to begin the moment hostilities cease.

No one should be under any delusion on this point: the Germans and Austrians expect to be fought and expect to fight commercially, after the fighting on the battlefields is over. In England some people may imagine that both Central Empires have had enough of war in every sense of the phrase, but judging from the occasional speeches of statesmen and other signs, this is as far as possible from being the case. Both the Central Empires—Austria under the direction of Germany, are busy already, and have long been busy preparing for the commercial fray. Throughout the British Empire this aspect of affairs should be kept constantly in view, and our whole commercial policy directed accordingly.

Current events indicate that the Allies will have something in the way of a counter argument to offer against the best laid plans of our enemies, but the proximity of Canada to the United States, and the neutrality of that country render it a most desirable rendezvous from which enemy agents will continue the struggle after peace comes.

Much business has been and will continue to be done between here and the States, but if such business happens to be done with disguised Teutons who outrage the hospitality and flaunt the laws of their pro-tem fatherland, the severing of business relations with all such concerns does not constitute a violation of moral right any more than does the annihilation of an enemy outpost. The fact that it is done at the request of our Government shows that it is a duty to the nation, while if done voluntarily it would be no more than an expression of individual opinion. In other words, people who trade with Germany, help to sustain her in the struggle, therefore, why question our right to refuse to help those who help our enemies.

### SHELL COMMITTEE VINDICATED

**G**IVING evidence of careful preparation, the Meredith-Duff Commission Report regarding the disposal of fuse contracts has made its appearance. Taking account of the duration of the inquiry, the number of witnesses and the volume of evidence forthcoming, it may be said that considerable despatch has marked the whole transaction. An analysis of the Commission finding discloses little, if anything, contrary to well-formed public opinion antecedent to and during the investigation proceedings.

It is a matter of considerable satisfaction, however, to the clientele of this journal that the integrity and honesty of purpose of the Shell Committee, individually and collectively, have been publicly vindicated, and from our personal knowledge, a still greater satisfaction will be felt by each of the gentlemen concerned. The Commission proceedings and findings have not been without their redeeming and compensating features, serving as they have done to bring into greater relief and to give that deserved prominence to ungrudged service to our Empire during a highly crucial period.

## INDUSTRIAL NOTABILITIES

**B**ASIL MAGOR, C.E., vice-president and general manager, National Steel Car Co. of Canada, manufacturers of railroad cars and motor trucks, Hamilton, Ont.; and president, Magor Car Co., New York, was born in Montreal, June 11, 1870, the son of John and Jane (Schroeder) Magor. He was educated at High School, Montreal; Rensselaer Polytechnic Institute, Troy, N.Y., graduating in Civil Engineering in 1894.

He spent four years as an apprentice with the Grand Trunk Railway, Montreal, 1884-1888; attended College at Troy, N.Y., 1888-1890; engaged for two years as engineer on World's Fair Buildings at Chicago, 1890-1892; returned to college, 1892-1894; and after graduating spent several years as engineer under Wm. Barclay Parsons, chief engineer on New York's first city subway, 1894-1898.

BASIL MAGOR

Mr. Magor next took an engagement on the survey of 740 miles of railroad work from Hankow to Canton, China, for a New York syndicate; this railroad has since been purchased by the Chinese Government. Following this he returned to New York and became a partner in the firm of Wonham & Magor, railroad supplies, 1900-1909. In the latter year he organized the Magor Car Co., of New York, of which he became president and general manager.

Early in 1912 Mr. Magor came to Canada to promote the National Steel Car Co., which was incorporated in July, 1912. The building was started in September of the same year, and the first completed car delivered in July, 1913. There has been recently added the building of motor trucks to the business.

Mr. Magor is a member of the Hamilton Board of Trade, the Canadian manufacturers' Association, and of the American Society of Civil Engineers. His clubs are Racquet and Tennis, and University, New York; the Tamahaac, Caledon Mountain Trout, Hamilton, and Hamilton Golf, all of Hamilton, Ont.; the Montreal Golf and Ottawa Country.

In politics he is Independent, and in religion an Anglican.

He married Ruth Chamberlain, daughter of H. P. Chamberlain, Buffalo, N.Y., on June 15, 1907, the family consisting of three girls. His residence is 42 Charlton Avenue East, Hamilton, Ont.

Prices Per Lb. Unless Otherwise Stated.

quoted. Large orders have recently been placed here for cars, both for home and foreign use. Pittsburg prices on black, and blue annealed sheets have been advanced \$3 per ton, the prices asked being 3.15 for black and 3.25 for blue annealed. The recent decline in the spelter market has somewhat disorganized the situation regarding galvanized sheets. Some large interests are insisting that buyers accept shipment of material, contracted for when prices were much higher; in fact several cases of litigation are pending. Wire and wire products are at present quiet, as is general during the summer months, but as the fall requirements begin to come in, the indications are for another advance. Boiler tubes are fairly active, and other steel and iron products are comparatively bright.

## Metals

Slight improvement is shown in the general situation, and although no material change is made in prices the tone is apparently better. Copper is quiet, but steady. Tin is much stronger and advances are general. Spelter is resuming its former position with advancing prices. Lead is quiet but steady. Antimony refused to respond and continues to decline.

## Copper.

The market at present is quiet but shows some signs of becoming steadier. Producers are firmer in asking prices, but inquiry from consumers is apparently light. The bulk of the sales are being made to dealers who have recently been disposing of metal at lower prices than the market quotations. The firm attitude shown by the large producers seem to indicate that higher prices are not improbable, the firm tone generally appearing to foreshadow a slight advance. London cables show a firmness in spot, but futures have declined 10 shillings, and electro spot is £2-10 lower, the latest quotations being £91, £89 and £122 respectively. New York reports a decline of 1c on prime lake, and ½c off electrolytic and castings; the current nominal quotations being 25½, 25 and 23 respectively. Local dealers are holding firm at 31c for lake and electro, and 30c. for castings.

## Tin

The market is showing signs of steadying after a period of dullness. No considerable buying has developed but consumers are showing interest in the recent decline and buying activity is expected. Quiet purchases in small lots are reported, and sales for future delivery are fairly good. London cables show a decline on the week of 15 shillings on Standard spot, but on Wednesday of last week the quotation was as low as £163. Futures dropped to £163½ but latest reports are quoting £168¾.

## The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

**Montreal, July 24, 1916.**—The industrial situation retains the activity it has shown for many months, and with the exception of some slight relaxation, due to the hot weather and holiday season, the pressure of business continues to be as great as ever. A serious break in the Lachine Canal has resulted in tying up a large number of vessels, to and from the Great Lakes, with the result that shipments of grain, coal, etc., has been much delayed. The situation is being gradually relieved as the water is admitted as the coffer dam is constructed, allowing low draft vessels to proceed on their course. It is expected by the middle of the week the damage

will be repaired and normal conditions resumed.

## Steel

The chief feature in the steel situation is the large volume of export business and the constant inquiry for foreign shipment. Domestic activity is not very great, consumers being well covered for immediate needs. The production end of the steel business is experiencing some difficulty due to the falling off in output owing to the extreme heat. The demand for billets and sheet bars is very good, especially for foreign shipment. The requirements of plate users are enormous and in some instances higher prices are being paid than those

Straits spot, which was as low as £164 during the week is now quoted at £169¼. New York prices weakened during the week, but a recent advance has again placed quotations at last week's figures of 38¼ c. per pound. Local dealers report a fairly active market with prices firm at 44 c. per pound.

#### Spelter

The steady tone of spelter continues and the market is gradually resuming its position among the other metals. Everything seems to point to a continued buying of spelter, as inquiries both from home consumers and abroad are constantly increasing. While many think that the sudden change is an effort on the part of producers to frighten the trade into the buying of metal, there appears to be every reason to believe that the market is firm and the improvement quite legitimate. Producers are apparently well sold up and the demand from abroad is quite heavy. The sharp break recently noted in the London situation made it appear that the market was over supplied, but the latest advances seem to contradict this as London reports show an advance on the week of \$7 on spot and \$6½ on futures. Latest quotations are \$54 for spot and \$50 for futures. New York price of 10.675 shows an increase of 1⅞ c. per pound. Local dealers report improved conditions with increased activity and are quoting 16 c., an advance of 2 c. over last week.

#### Lead

The situation in lead is very quiet, and with the exception of a few export orders, the activity is not pronounced. The Trust retains its firm attitude but declined another ⅓ c. Local dealers are firm at 9 c. per pound.

#### Antimony

The market continues stagnant and prices are still declining. The prospect of further shrapnel requirements was expected to strengthen the market but the contrary has been the case and the situation is becoming weaker. The increased use of high explosive shells has been the cause of the relative decline in the demand for antimony. New York quotations have again declined, the latest quotation of 13½ c. being a drop on the week of one cent. Dealers here report a very quiet market and have declined in their quotations to 20 c., a drop of 2 cents per pound.

#### Aluminium

No change is noted in aluminium and quotations are firm at 65 c. per pound.

#### Machine Tools and Supplies

Owing to additional orders having been placed for the heavier shells, inquiries for suitable equipment have shown some improvement. A feature of the present situation is the supply of re-sale tools which have done duty in the

production of small shells, and the supply of these tools has resulted in substantial reduction in the prices asked. This feature has not affected the new machine market as builders are fairly well covered by future business. The demand for supplies continues very good with the question of delivery gradually resuming more normal conditions.

#### Scrap

The situation in the scrap and old materials is practically unchanged. Some consumers of heavy melting steel are showing a little interest and dealers are asking slightly higher prices. The tone of the general market in old materials is very quiet and prices are inclined to weaken, but any inquiry seems to bring out the fact that quoted prices are subject to change at a minute's notice. New York quotations on brass scrap have fallen off from ¼ to ½ c. per pound. Aluminium has declined one cent for old cast and 2 c. for old sheets. Following the renewed strength in spelter, scrap zines have ad-

#### CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion \$100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

vanced from 1½ to 2 c. per pound. The situation here is unchanged and prices are firm with the exception of scrap zinc and aluminium, which are quoted at 8½c and 34c, an advance of 1½c and 1c respectively.

Toronto, Ont., July 25.—The manufacture of munitions is still the most important feature in industrial circles, and indications point to the present activity continuing well into 1917. The credit which has been established by the Dominion Government will allow of further large orders for shells, running into many million dollars, being placed in Canada. The shells will be principally of large calibre, 6 in., 8 in. and 9.2 in. and will, of course, require a considerable quantity of steel. This will also mean further orders for machine tools, principally heavy duty lathes and drills. The chief difficulty now being experienced in keeping the output of munitions up to the required standard is the scarcity of skilled workmen. The only solution of this problem seems to be the dilution of labor as is employed in the Old Country. A considerable number

of girls and women are already employed in shell factories in Canada and more will no doubt be utilized for this purpose.

#### Steel

The greatest activity prevails in the steel trade and the outlook is unusually favorable. The steel companies are getting more orders than they can handle for some products, especially rails and shell steel, and have been obliged to place some of their contracts in the United States. The C. P. R. is expected to place a large order for rails in the States. A firm of car builders has purchased 28,000 axles with wheels from U. S. concerns, and it is reported that a Canadian mill, presumably the Algoma Steel Corporation, being unable to buy blooms in the States to fill contracts from American railroads is endeavoring to place the rails there. As regards ordinary business such as merchant bars, plates and shapes, the market is quiet as is usually the case at this season of the year. There are no price changes to report this week but quotations continue very firm. The demand for boiler tubes is active in the primary market in spite of the fact that makers of both locomotive and merchant tubes are sold up for five or six months, and are much behind on deliveries. Prices on wrought iron pipe are unchanged but a decline in galvanized pipe is looked for in the near future on account of the weakness in spelter. The skelp situation is unchanged, this material being still difficult to obtain.

Prices on galvanized sheets are weak due to the decline in spelter and further reductions are probable. In the States the price of galvanized sheets, No. 28 gauge base, continues to follow the fluctuations of the spelter market. As quotations on black sheets are practically stationary, the cost of coating is the determining factor in fixing galvanized prices. Blue annealed sheets, particularly in the large sizes of the heavier gauges are in good demand, but black sheets are quiet. Prices of sheet bars are still high and irregular.

In the United States the steel market is stronger as a result of curtailed production due to hot weather, and also because of large export business in steel products particularly shell steel and rails. Domestic demand is lighter than usual, summer dullness having settled over the steel trade, nevertheless a buying movement is looked for early in September. Inquiries are pending for about 18,000 tons of structural material from Canada, and Canadian buyers also want large quantities of billets. Bars have declined, and are now quoted at 2.50 c. but plates and shapes are unchanged at 3.50 c. and 2.50 c. respectively f. o. b. Pittsburgh.

### Pig Iron

The pig iron situation is unchanged and the market is quiet, there being nothing of particular importance to note. Quotations are unchanged, Hamilton No. 1 being quoted at \$24, and Victoria No. 1, \$25 per ton.

### Machine Tools

The market is more nearly normal as regards the volume of business although the demand is almost entirely from munitions concerns. On account of the orders for shells that are being placed from time to time, it is anticipated that there will be a steady demand for suitable machine tools for some time to come this will keep the market active. The demand in the States for machine tools is considerably lighter than it was, and makers are consequently able to make quicker deliveries. Canadian machine tool builders although exceptionally busy are able to make pretty good deliveries. Although prices of second hand equipment have declined there is some talk of further advances in new tools.

### Metals

There is a little improvement in the situation but prices continue to decline in some metals such as copper and antimony. Copper buying continues on a restricted scale with second-hands offering concessions. Tin is also weak on light demand but there is a better undertone to the market. Spelter, although lower is also showing indications of a recovery. Lead is unchanged but there is a possibility of lower prices in the near future. Antimony has declined gain but aluminium is unchanged. Solders are unchanged.

### Copper

Quotations continue entirely nominal and are slightly lower. Consumers are taking very little interest in the market, and resale lots are being offered at concessions. Local quotations are lower at 29 c. per pound.

### Tin

Although the demand is light, the market is more active which has tended to stop the recent downward movement. Local quotations are unchanged at 44c. per pound.

### Spelter

The market is firmer as consumers are taking more interest in spelter, particularly the galvanizing interests. Quotations are unchanged at 14c. per pound.

### Lead

The market is dull and unchanged with light demand. There is some possibility of the leading interests lowering their prices. Locally lead is unchanged at 9c. per pound.

### Antimony

Quotations are lower and entirely nominal with the market dull and weak.

Antimony is now being quoted at 20c. per pound.

### Aluminium

The market is quiet and unchanged at 67c. per pound.

## CONCERNING ALUMINIUM.

IN a recent note to the Faraday Society on the annealing of aluminium, Messrs. Seligman and Williams describe certain interesting anomalies in the behaviour of the metal. Hard-worked aluminium is more readily soluble in nitric acid than the annealed metal. On heating the hard-worked metal to 125 deg. Cent., a definite change in the rate of dissolution is brought about. A sample of the hard-worked metal which lost 56 mgr. per 100 square cm. per 24 hours in 1.42 nitric acid lost 39 mgr. when similarly exposed after being annealing for 10 hours at 125 deg. Cent. there was a decrease in the rate of dissolution of 5.3 per cent.

It was anticipated that if the heating were prolonged the decrease in the rate of dissolution might be augmented. This was not found to be the case, but, on the contrary, as the heating at 125 deg. Cent. was prolonged, the fall in the rate of dissolution diminished until samples heated for 80 hours at 125 deg. Cent. showed the same rate of dissolution as, or even a slightly higher rate of dissolution than samples which had not been heated at all. These facts do not tally completely with the observations of other workers.

## NOVA SCOTIA STEEL PROPERTIES AND PROSPECTS

THE directors of the Nova Scotia Steel & Coal Co., has just completed a trip of inspection to the various properties of the company at Wabana, Sydney Mines and New Glasgow. One of the leading interests discussing the trip, says:—

"At Wabana we found that, while the quantity of ore being mined is much less than under normal conditions, a considerable amount of new territory has been opened up during the past year in the submarine workings both east and west of the main slopes. All the levels driven have continued in ore from 18 to 32 feet high, all of which is clear and high-grade from pavement to roof. Electrically operated power excavating shovels are working at both the east and west faces, loading ore direct into cars. Rapid progress has been made with the pair of new slopes, work on which is being driven from three points, with a weekly advance of 60 to 68 feet on each of the three sections.

At Sydney Mines while the coal output is not equal to that in pre-war times, owing to the shortage of labor, the out-

put of steel is much greater. An inspection was made of the new blast furnace in course of construction.

At New Glasgow the entire plant is making a record production, while the Eastern Car Co., a subsidiary, is working at high pressure on large foreign government orders. At the moment it is understood that the company is in close negotiation with two foreign governments for further orders."

Indications point to the fact that Scotia has actually booked at the present time business amounting to nearly four times that of any normal year in value.

## CONSULAR DOCUMENTS

ALTHOUGH consular invoices may sometimes be certified by foreign government representatives in interior cities of Canada, it is, in most cases, better to have such documents certified at the port of shipment. It is not possible to give any general rules for the arrangement of consular invoices as different countries require different specifications. Invoices of most countries may be arranged in English. It is necessary to describe in most consular invoices the exact character of the goods shipped.

Many of the Latin-American countries allow shippers to arrange their consular documents in English, although the language of the country may be Spanish or Portuguese. If, however, the consignee requests that the consular documents be arranged in Spanish or Portuguese, this should be done, even though, as far as the consular regulations are concerned, it is optional with the shipper whether they are made out in English or some other language. Sometimes, as is the case with Brazil and Cuba, the government makes an "official" charge for the translation of shipping documents in a foreign language, which charge is usually much higher than the cost of making out the documents in the language of the country if done by the shipper. The consignee should, of course, be billed with the extra expense that he thus places upon the shipper.

When consular invoices are required to be arranged on a foreign language, great care must be taken in the translation of same, so that the foreign words used convey precisely the English meaning. In arranging consular invoices there must be no erasures or corrections or writing between the lines.

## MINIMUM BILLS OF LADING

THE rates quoted by various transportation companies for minimum bills of lading and parcel receipts are subject to change at the discretion of the company issuing same, or through fluctuations in

the rate of freight or exchange. Some steamship companies, in fact, have no fixed minimums, and will, on occasion, quote as low as may be required to secure the shipment. During the war in Europe, steamship lines are liable to increase the cost of their minimum bills of lading, even to non-belligerent countries, owing to the increased cost entailed by war insurance on the steamer, possibility of seizure, detention, etc.

A minimum bill of lading is the least sum of money for which a steamship company will take the responsibility of issuing a bill of lading. With the transatlantic lines this amount is usually one guinea (about \$5.10) for direct ports, and with South American lines, \$5.00. For ports not actually called at by the steamers of the lines, the minimum bill of lading is the sum of the minimum to the port where transshipment occurs and the minimum from that port to final destination. The minimum from the port of transshipment to final destination may be either greater or less than the minimum to the direct port, which accounts

for the apparent discrepancies in minimums to the same place by different lines.

Any shipment which, according to the freight rate (weight or measurement), amounts to less than the minimum charge has to pay the full minimum. Small shipments, however, can sometimes be made on "parcel receipts," but such shipments must be of small weight, dimensions and value, and the responsibility of the steamship company is much less under a "parcel receipt" than under a bill of lading.

#### MARKING OF PACKAGES

ALL goods must be distinctly marked with the port of destination. The marking of packages plays a more important part in export shipping than most Canadian manufacturers are willing to believe. For instance, in shipping to several South American countries all the marks on the packages must be stenciled, brush marking not being allowed. Other countries require that the marks, numbers, etc., must be placed on two or

more adjacent sides of the packages. Others again require the net and gross weights in kilograms on each package, also a number which must correspond with the number of the package as given in the consular documents. Failure to observe these regulations always results in fines, delays, and annoyance at destination.

In connection with marking cases, it is of the greatest importance that nothing but the shipping marks, such as appear on the invoice and the bill of lading, be put on the cases, otherwise the importer is liable to a fine. Frequently manufacturers use second-hand cases on which there are many old marks, so that it is often difficult to make out the proper ones. These superfluous marks and numbers cause much trouble in the custom house and oftentimes expense to the importer.

Some manufacturers have a weakness for stenciling or printing the contents on the sides of the cases, which they think will serve as an advertisement.

## CANADIAN COMMERCIAL INTELLIGENCE SERVICE

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

# INDUSTRIAL <sup>A<sub>N</sub>D</sup> CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

## Electrical

**West Lorne, Ont.**—The Village Council will spend \$8,000 on the installation of a hydro-electric system.

**Earl Grey Sask.** — The village council contemplate installing an electric light plant to cost about \$2,000.

## Engineering

**Ottawa, Ont.**—The Chevrolet Motor Co., will shortly begin the construction of an addition to their plant here to cost about \$40,000.

**Orillia, Ont.**—The E. Long Co. have secured the old wheel works building of the Tudhope-Anderson Co., and will instal a machine shop there.

**Vancouver, B.C.**—The Granby Consolidated Mining & Smelting Co. will instal a steam power plant at the Anyox Smelter to be used as an auxiliary during the winter.

**Shawinigan Falls, Que.** — A power house at the plants of the Northern Ammunition Co., was struck by lightning recently and some of the electrical equipment damaged.

**Hamilton, Ont.**—Fire on July 21 completely destroyed the Brown-Boggs Co. factory on King William Street. The loss, including the damage to the machinery is estimated at \$75,000.

**Edmonds, B.C.**—The Olympic Metals Co. has taken a lease on the Edmond Electric Power Building and will remodel it for the installation of a modern metals refining and smelting plant.

**Port Arthur, Ont.** — The C. N. R. will make an extension to the round-house and build a machine shop here. Particulars may be obtained from T. E. Nelson, superintendent, Port Arthur.

**North Bay., Ont.** — The Donohoe Mines Corporation are making arrangements to install a 50 ton concentrator for the treatment of such ores from the mine as do not carry heavy lead values.

**Trail, B. C.** — It is anticipated that the copper refinery which is being built here will be in operation early in August. The plant will have an initial capacity of 10 tons of pure copper daily.

**Stump Lake, B.C.**—A Seattle syndicate has taken over the property of the Nicola Mining & Smelting Co. at Stump Lake, near Kamloops, B.C., and will instal a 100-ton concentrator plant and other machinery.

**Winnipeg, Man.** — General Manager McLeod, of the C. N. R., has signed contracts for the erection of a large machine shop and stores at Edmonton. The contract price is \$65,000, and Nesbitt & Co. the successful tenderers.

**Toronto, Ont.** — A permit has been issued to the Toronto Harbor Commissioners, to erect one-story brick tile and stone addition to blacksmith and machine shop on the Don diversion of the channel, at the foot of Cherry street, at a cost of \$2,700.

**St. Thomas, Ont.** — The American Brake Shoe & Foundry Co., whose head office is in New York, will establish a foundry here for making brake shoes and miscellaneous castings. The foundry will be 225 ft. by 50 ft., and will be located near the Canada Iron Corporation's plant.

**Newcastle, N. B.** — The villages of Richibucto and Rexton have been incorporated as a hydro-electric power company, to dam the Kouchibouguac and generate electricity for light and other purposes. It is a Nova Scotia project to generate enough current to light Chatham and Newcastle.

## Municipal

**Montreal, Que.** — The City Council propose spending \$10,000 on water meters.

**Peterborough, Ont.** — The City Council are considering the purchase of a motor truck for the fire department.

**Port Arthur, Ont.**—A by-law has been passed by the council to give a bonus of \$25,000 to the Western Drydock & Shipbuilding Co.

**New Toronto, Ont.** — The Village Council has decided to purchase a new pump for the waterworks system. It will have a capacity of 600 gallons per minute.

**Renfrew, Ont.**—A by-law is contemplated to raise \$200,000 to purchase the first chute water power on the Bonne-

chere River and to develop it for the production of hydro power, and to purchase the fourth chute water power also, though not to develop it at present.

**St. Thomas, Ont.**—A by-law will be submitted to the ratepayers providing for a loan to the Monarch Knitting Co. of \$30,000 for five years without interest. It is proposed also to give the company a fixed assessment for ten years of \$10,000.

## General Industrial

**Almonte, Ont.**—The Town Council are considering the installation of a Hydro-Electric plant.

**Walkerville, Ont.**—Walker & Sons will build a factory for the McCord Mfg., to cost about \$20,000.

**Stratford, Ont.**—The Hydro-Electric Commission will build an additional distribution plant here.

**Brandon, Man.**—The City Council are considering the purchase of a four-million gallon turbine pump.

**Toronto, Ont.**—The Toronto Carpet Mfg. Co. will build an addition to their factory on King Street West.

**Hamilton, Ont.**—F. F. Dalley will build a factory estimated to cost \$100,000. H. G. Christman & Co. are the contractors.

**Doon, Ont.**—The Doon Fibre Co. plant was practically destroyed by fire on July 22. The loss is estimated at \$40,000, with only \$5,000 insurance.

**Toronto, Ont.**—A building permit has been issued to the Ideal Bread Co., to alter a bakery on Argyle street and Dovercourt road, at a cost of \$3,000.

**Vancouver, B.C.**—The British Columbia Sugar Refinery has taken out a permit for an addition to the factory on Powell Street, the cost of the work being \$2,000.

**St. Catharines, Ont.**—The Chemical Refineries may shortly reopen their factory, which has been closed for some months. The company make potash from wood ashes.

**Orangeville, Ont.**—The Canada Clock Co., a recently incorporated concern, with a capital of \$250,000, proposes to establish a factory here for making clocks. A by-law will be submitted at

## 28" Duplex Helical Drive Engine Lathe for Band Turning

OUR unbounded confidence assures us that in a comparative test this machine would always stand paramount. Think of your present or proposed output, and compare it with 110 bands, with band turning equipment installed, per 10-hour day. That is what this machine is doing. Inspect the machine—superior quality will always stand the most rigid test—and when you have studied its features, its ordinary parts, its very construction you will be convinced that this is the machine for your requirements. It is specially adapted to band turning because of the worm drive on the main spindle; this prevents that undesirable chattering tendency. Complete band turning equipment can be supplied in a semi-finished condition.

The A. R. Williams Machinery Co., Limited, 64-66 Front St. W., Toronto

## "Here is a Die Head that you can depend upon" A Geometric Self-Opening and Adjustable Screw-Cutting Die Head

They are being used with absolute satisfaction on every make of Screw Machine.

A micrometer adjustment makes possible quick and accurate variations for a tight or loose-fitting screw. The chasers open automatically, so that no backing off occurs to injure the thread. Length of thread accurately governed—short or long.

Arranged for cutting any diameter, pitch and form of thread. Right or left-hand. Flush to shoulder, where required.

Let us recommend the right sort of Die Head for your work.

**The GEOMETRIC TOOL COMPANY**  
NEW HAVEN, CONN., U.S.A.

CANADIAN AGENTS: Williams & Wilson, Limited, Montreal.  
The A. R. Williams Machinery Co., Limited, Toronto, Winnipeg, St. John, N.B.

*If any advertisement interests you, tear it out now and place with letters to be answered.*

## A "money back" guarantee

**Y**OU take no chances when you supply your workmen with "Delta" files. You can't lose a cent. If for any reason a file bearing the "Delta" mark on the tang fails to give absolute satisfaction, we will refund its price.

We know what we are doing when we make this offer. We have been making files for 50 years, and so have learned to make them good.

We claim for "Delta" files that they are not equalled in cutting ability, in durability, and in fast-working quality by any other file made.

"Delta" files are the only ones made from 3 to 24 inches of crucible steel.

**Y**OUR workmen can accomplish more in an hour with a "DELTA" file than with any other file made—this on a test. A shape and size for every purpose.

Sold by all good dealers.

## DELTA FILE WORKS

PHILADELPHIA, PA., U.S.A.

an early date to provide for a free site, exemption from taxation and a loan of \$15,000. Messrs. Watson & Tannehill, of Toronto, are interested in the proposition.

## Tenders

**Beauceville, Que.**—The foundry owned by Marcoux & Poirer was destroyed by fire recently, the loss being estimated at \$12,000.

**Matheson, Ont.**—Tenders will be received until August 8 for the construction of a waterworks system. Particulars may be obtained from McAuslan & Anderson, North Bay, Ont.

**Seagrave, Ont.**—Tenders will be received until August 8 for the construction of a 50-ft. bridge across the Nonquon River, near here. Full particulars may be obtained from the engineers, Bowman & Connor, 31 Queen Street West, Toronto, or the county clerks at Lindsay and Whitby, Ont.

**Toronto.**—Tenders will be received by chairman Board of Control, City Hall, Toronto, up to August 1 for the supply and delivery of air brake equipment, step and door operating mechanisms, gears and pinions. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

**Toronto.**—Tenders for the erection of a court house at Sault Ste. Marie, Ont. (separate tenders are required for the heating and ventilating and plumbing and electric wiring) will be received up to August 1. Plans and specifications can be seen at the office of the sheriff, Sault Ste. Marie, and at the Departments of Public Works, Ontario Parliament Buildings, Toronto.

**Winnipeg, Man.**—Tenders will be received until August 21 for the various works required in the completion of the New Parliament Buildings, and not included in the general contract. The works include structural steel, heating and ventilation, electrical conduit and wiring. Particulars may be obtained from S. C. Oxtun, Deputy Minister of Public Works, Winnipeg.

**Lethbridge, Alta.**—Tenders will be received up to August 5 for the complete installation of a filtration system, capacity three million Imperial gallons per twenty-four hours. Plan showing location of buildings and elevations can be had by making application to the Public Works Department. A. M. Grace, Commissioner of Public Works.

**Ottawa, Ont.**—Tenders addressed to J. W. Pugsley, secretary, Department of Railways and Canals, Ottawa, Ont., will be received up to August 7 for the con-

struction and erection of passenger station at Halifax, N.S. Plans, specifications and blank form of contract may be seen at the offices of the following: Chief Engineer, Department of Railways and Canals, Ottawa, Ont.; Chief Engineer, Canadian Government Railways, Moncton, N.B. Superintending Engineer, Halifax Ocean Terminals, Halifax, N.S.; Ross & Macdonald, architects, Montreal and Toronto. Contractors who wish to obtain plans and specifications temporarily for their own use, may obtain same from Ross & Macdonald, Montreal, on depositing with them a certified bank cheque for \$100, which will be refunded on the return of the plans and specifications to them.

## Personal

**Paul Mercier**, chief city engineer, of Montreal, has asked the Board of Control to appoint a consulting engineer to oversee all the activities of the Public Works Department, and report thereon to the Controllers.

**Ernest G. Barrow, C.E.**, late city engineer of Hamilton, Ont., died in Toronto on July 21. The deceased was born in Bristol, England, in 1846, and came to Canada in 1871. He was appointed city engineer of Hamilton in 1896.

**Harold K. Beach**, until recently connected with the staff of Lockwood Greene & Co., New York, has been appointed mechanical superintendent of Brown's Copper and Brass Rolling Mills, New Toronto, Ont.

**Sir Rider Haggard**, honorary representative of the Royal Colonial Institute, who has been visiting Canada for the purpose of investigating conditions and facilities offered for proposed land settlements for British soldiers after the war, sailed from New York on July 22 for England.

## Marine

**The Taylor Engineering Works**, of Vancouver, B.C., has received the contract for supplying two 160 h.p. Bolinders crude oil engines for the Cameron-Genoa Mills Shipbuilding Co., and six engines of the same type for the Wallace Shipyards.

**Kaministiquia Channel.**—President Livingstone, of the Lake Carriers' Association, is advised by the Canadian Department of Marine and Fisheries that the dredging of the northerly half of the entrance channel to the Kaministiquia River to a depth of 25 feet has been completed and tested by sweeping. The whole entrance between the buoys is now 25 feet deep, with a width of 600 feet up to the Empire Wharf.

## Contracts Awarded

**Brantford, Ont.**—The contract for the erection of the new School of Mines at Haileybury, Ont., to cost \$20,000, has been awarded to P. H. Secord & Sons, of this city.

**The Foundation Company, Montreal,** has received two contracts from the Algoma Steel Corporation, Sault Ste. Marie, Ont. One is for the revision of the yard, including the engineering and constructing of three plate-girder bridges, and the other is for the construction of the foundations of two open-hearth furnaces and a gas producer.

## Wood-Working

**Springhill, Que.**—The saw mill owned by D. M. McDonald has been destroyed by fire.

**Montreal, Que.**—The St. Lawrence Wagon Co. will build a factory here at a cost of \$7,000.

**Harrow, Ont.**—C. F. Smith, proposes to rebuild his planing mill, which was recently destroyed by fire.

**Jaffray, B.C.**—A hurricane blew the top off the East Kootenay Lumber Co. mills here, and set fire to the building, which was totally destroyed, with five C.P.R. cars.

**Calgary, Ala.**—Tenders will be received until August 8. for the construction of a Drill hall here. Leo Dowler, of Calgary is the architect. The cost is estimated at \$250,000.

**Vancouver, B.C.**—Fire practically destroyed the sash and door factory of W. G. Scrim & Co., on July 7. The loss is roughly estimated at \$9,000. This includes damage to the stock, about \$5,000, and damage to the building the remaining \$4,000. The stock, it is understood, was insured for about \$3,000.

## New Incorporations

**The Commercial Acetylene Railway, Light & Signal Co.** have been granted a license to carry on business in the Province of Ontario.

**La Compagnie d'Automobiles Agricoles Bruneau** has been incorporated at Ottawa, with a capital of \$100,000, to manufacture steam, oil and gas engines, and automobiles, etc., at Danville, Que. Incorporators: G. N. Letendre and E. T. Bruneau, of Danville, Que.

**The Orillia Worsted Co.** has been in-

corporated at Ottawa, with a capital of \$300,000, to manufacture woollen, worsted and cotton goods of all kinds at Orillia, Ont. Incorporators: Melville B. Tudhope, George Rapley and Robert Wade, all of Orillia, Ont.

**The Pine Lake Lumber Co.** has been incorporated at Toronto, with a capital of \$60,000, to carry on a lumbering business and operate saw and planing mills at Pickerel Landing, Ont. Incorporators are: F. A. Hammond, H. B. Palen and J. McIvor, all of Toronto.

**British Acetones of Toronto** has been incorporated at Toronto with a capital of \$50,000, to manufacture explosives, including acetone, etc. The head office is at Toronto, and the provisional directors are: Thomas P. Galt, George E. McCann and A. L. Brooks, all of Toronto.

**The Canada Stove & Foundry Co.,** has been incorporated at Ottawa with a capital of \$1,500,000 to carry on the business of iron masters, steel makers, Head office to be situated at Montreal, Que. Incorporators, E. R. Parkins, R. E. Allan and F. W. Toffield all of Montreal.

**Deloro Smelting & Refining Co.** has been incorporated at Ottawa, with a capital of \$1,500,000, to acquire and take over the Deloro Mining & Reduction Co. Head office to be situated at the Village of Deloro, Ont. Incorporators: S. King, O. H. King and Herman S. King, all of Toronto, Ont.

**The Chipman-Holton Knitting Co.** has been incorporated at Ottawa, with a capital of \$1,000,000, to manufacture all kinds of knitted goods and textiles. Head office to be situated at Hamilton, Ont. Incorporators: F. L. Chipman, of New York, and William A. Holton and M. Baldwin Holton, of Hamilton, Ont.

## Railways—Bridges

**Ottawa, Ont.**—It is expected that the Quebec & Saguenay Railway line to Murray Bay will be completed by Nov. 1.

**Ottawa, Ont.**—The Toronto Harbor Commissioners have deposited with the Public Works Department plans for the railway bridge proposed to be built across the Don in the Toronto Harbor Industrial district.

**Moose Jaw, Sask.**—The C. P. R. have let the contract for the completion of the Assiniboia branch from Vantage to Assiniboia, a distance of eight miles, to W. H. Dutton & Co., of Winnipeg. The completion of this line will give Moose Jaw direct connection with Lethbridge.

## Oxy-Acetylene Welding

We can give the best of service in all kinds of welding repair jobs. We have successfully repaired the most difficult jobs. Our work is high-class and our prices moderate.

## KEYSEATER

for Milling Internal  
Keyseats

This tool is an attachment for the drilling machine, and is regularly made with straight shank for gripping in the drill chuck; taper shank can be had if desired. The tool is fitted with a high-speed steel rotary cutter for milling internal keyseats in one cut. To complete a keyseat it is only required to pass the tool through the hole just once. Innumerable inexpensive eccentric bushings are supplied whereby the tool may be bushed to meet any diameter above its own.

Write for Catalog C for full detail.

143-153 University Ave., Toronto, Can.

**Vancouver, B.C.**—The Northern Construction Co., of Winnipeg and Vancouver, is interested in the contract for the erection of the million dollar Canadian Northern depot at Vancouver, their tender having been accepted jointly with that of the Carter-Halls-Aldinger Co., of Winnipeg.

**Toronto, Ont.**—The Scarborough Township Council has decided to ask tenders for two bridges to be built in the township, one at Scarboro' and the other across the River Rouge. Petitions were also received from Scarboro' Junction and Agincourt asking that the Hydro power be used in both villages for street lighting and domestic purposes.

**Ottawa, Ont.**—The linking-up of the Canadian Northern lines, between Toronto and Montreal and Quebec, involving the completion of the Mount Royal tunnel terminal scheme is being hastened by the C. N. R. in connection with the financial assistance, recently granted to the company. Both the company and the Government regard the early completion of the tunnel as of primary importance in ensuring the success of the whole scheme.

## Trade Gossip

**Credit Men's Officers.**—At the annual meeting of the board of directors of the Canadian Credit Men's Association in Toronto, the following officers were appointed: President, W. H. Lamont, succeeding H. D. Eby. Mr. Eby continues as director. Vice-president, James A. Catto; secretary-treasurer and manager, A. S. Crighton.

**C. P. R. Convention.**—The C. P. R. held a convention in Winnipeg last week for the purpose of exchanging views and devising ways and means of closer co-operation so that the company may get and keep in closer touch with the public. Over 150 officials from all parts of the system were in attendance at the meetings which were held at the Royal Alexandra Hotel.

**Big Windsor Merger.**—Details have been practically completed for the consolidation of the Kelsey Wheel Co., of Detroit and Memphis; Kelsey Wheel Co., of Windsor, Ont., and the Herbert Mfg. Co., of Detroit, into a new corporation, to be known as the Kelsey Wheel Co., Incorporated. The new company will have a capital stock of \$13,000,000. John Kelsey is to be president of the new corporation.

**The Ontario Hydro-Electric Commission** have secured from the Canadian Niagara Power Co. of Niagara Falls, Ont., a supply of 12,500 h. p. available from time to time as the Commission re-

quires it. The Commission may call for a further supply up to the amount now being exported from Ontario. This arrangement settles for the time being the question of exporting power from the Province and relieves a growing shortage of power.

**The Joseph Dixon Crucible Co.,** Jersey City, N. J., have appointed the Canadian Asbestos Co., Montreal, sole selling agents for all Dixon graphite productions with the exception of Dixon's lead pencils, erasive rubbers, crayons and penholders. This arrangement has been made in order to extend and increase their business throughout Canada and Newfoundland, and to be in closer and more frequent touch with all interested in graphite productions.

**The Turbine Equipment Co.,** Toronto, have received from the Algoma Steel Corporation, Saulte Ste Marie, Ont., contracts to supply one 15 million gallon De Laval single stage, double suction, centrifugal pump, direct-connected to one 550 h. p. Canadian Westinghouse motor; one 3 million gallon unit direct-connected to a 125 h. p. motor, and two 1 million gallon units to be direct-connected to 40 h. p. motors.

**Victoria, B. C.**—Owing to unforeseen delays the completion of the work on the Saanich observatory and the mounting of the huge telescope, the largest in the world, will be delayed longer than at first contemplated, and it will be well on in the Fall before the observatory will be ready for full operation. The chief delay has been occasioned by reason of the necessity of manufacturing on this side of the Atlantic the plain mirror to be used in testing the great concave mirror. This plain mirror is 55 ins. diameter and the concave mirror is 72 ins. diameter.

**The Potash Products Co.,** Vancouver, B.C., has developed a process whereby kelp can be handled in an economical manner, eliminating the excess of salt and slime, producing commercial potash as well as a dry kelp fertilizer which ranks higher in actual results than the German product. The great shortage of potash in this country has resulted in prices in the neighborhood of ten times normal figures which allow very large profits where a good supply is obtainable, although in actual figures the company bases its profits on normal quotations.

**Navigation on Hudson Bay.**—The Department of Marine and Fisheries, Ottawa, is preparing for the immediate opening of navigation on Hudson Bay and Straits. Travelling up by one of the tramp steamers carrying construction supplies is an officer of the Department who will put in operation a dozen light-

houses—ten in the Straits and two at Port Nelson. This year's tonnage promises to be small, and will be confined to a dozen tramp steamers. Next year when the Hudson Bay Railway and elevators are in operation the route will be put to a real test.

**Regenerating Sulphated Accumulator Electrodes.**—In the course of a research on lead sulphate and lead, G. A. Perley and C. W. Davis, of Durham College, New Hampshire, observed that sulphated electrodes of secondary batteries could be regenerated by being placed in caustic soda, without the use of an external current. The method, however, was not satisfactory, and after trying various solutions—sodium sulphate, chlorate, phosphate, carbonate, tartrate, etc., with or without the addition of caustic soda—they found that the old method of regeneration by sulphate of sodium was, after all, the best. They advise the placing of two additional positives next to the two outer negatives, in order to hasten the regeneration of these latter electrodes. The regeneration is effected by supplying the ordinary charging current for about 60 hours.

## Building Notes

**Winnipeg.**—On August 21, T. H. Johnson, Minister of Public Works, will receive and open in public tenders for completion of the Manitoba Parliament Buildings.

**Toronto, Ont.**—The Toronto Hydro-Electric Commission have applied for a permit to erect a four-storey addition to their sub-station at the corner of Duncan and Nelson streets, to cost \$90,000.

**Leather Belting.**—A new catalogue just issued by the Graton & Knight Mfg. Co., Worcester, Mass., illustrates in every respect just what a publication of this nature should be, for, besides featuring all the products made by the company, a great deal of space is devoted to facts of general interest to those who purchase belting, lace leather, packings and other leather products. The belting section of the catalog is of unusual interest to buyers of belting, as it not only describes the characteristic qualities of each grade manufactured, but also explains clearly and conclusively why these grades are essential, their particular differences and capabilities. This section also embodies valuable mechanical rules, tables and formulas, to further assist the buyer to determine the proper grade, width and weight of belting required for any given drive.

A special section of the catalogue is devoted to leather packings, describing all the various kinds, grades and the ad-

## Catalogues

**Tool Chests** made by the Union Tool Chest Works, Rochester, N. Y., Folder illustrating and describing many styles of tool chests for mechanics. Each style is illustrated and the dimensions are given for the various sizes.

**The Chain Belt Co., Milwaukee, Wis.,** have issued a new folder No. 64 describing traveling water screens designed primarily to remove refuse and foreign material from water before it enters power plants or any industrial plant requiring large quantities of clean water. Illustrations are included showing installations.

**T. W. Broadbent-Ltd., Huddersfield, England,** have recently issued a leaflet No. 1, being a section of catalogue No. 1, dealing with "D" type generators for continuous current. The leaflet contains a specification covering the principal features in the design while a price list and shipping particulars are also included. The leaflet is illustrated.

**Insuluminum.**—Bulletin 118, just issued by the Diamond Power Specialty Co., Detroit, Mich., contains a number of photo-micrographs and describes the properties of this new product of the General Electric Co.'s. laboratories, which will withstand a continuous temperature of 1800 deg. Fahr., as compared to 1200 deg. Fahr., for iron and steel. Photographs and records of a series of comparative tests at high temperatures of insuluminum and iron pipes, made by a number of well-known companies, are included. The bulletin is "readable." It deals primarily with the interesting new metal, but the application of the material to the Diamond Mechanical Soot Blower System is described briefly on the concluding page.

"The Logic of the Dean," is the title of an attractive new 20-page booklet just issued by The William B. Pierce Co., Buffalo, N. Y., illustrating and describing their Well-known "Dean" boiler tube cleaner. "The Logic of the Dean" is intended primarily for the management of the plant, although it contains a wealth of information of unusual value to the chief engineer or any of his assistants. The booklet, besides describing and illustrating the operation of the "Dean" cleaner, discusses the scale problem in detail. Some of

**Bucket Conveyors.**—The C. W. Hunt Co. Inc. West New Brighton, N. Y., have issued a catalogue No. 154 describing the "Hunt" noiseless pivoted bucket conveyor for handling coal, ashes, coke, phosphate rock, cement, clinker, etc. The catalogue has been issued with the object of suggesting to those operating or designing a power house the advantages and obvious savings possible with a properly arranged coal and ashes handling plant. The catalogue contains data valuable to an engineer in laying out a boiler house and a number of cuts showing different arrangements of the conveyors for various purposes. Several pages are devoted to reproductions of drawings showing conveyor details with dimensions. Other illustrations show driving mechanisms and valves etc.

## Book Reviews

"Water-Works and Sewerage Systems of Canada," by Leo G. Denis. This is a new edition which has just been issued by the Commission of Conservation. In the present report the various physical and financial data respecting water-works have been brought up to date and a new section on sewerage systems has been added. The book is a royal octavo volume, handsomely bound in cloth, contains 176 pages of text and is well illustrated with 25 half-tones and 5 diagrams. In the year of Confederation there were only 7 water-works plants in Canada; to-day there are 528. These have been built at a total cost of \$123,725,633 and entail an annual maintenance charge of \$4,558,539. The total daily consumption is 426,877,000 imperial gallons, which gives an average daily consumption per capita of 111 gallons, ranging from 50 gallons in Manitoba to 143 in New Brunswick. There are 206 plants supplied from springs or wells and 322 from lakes or streams. In 72 plants the water is filtered and in 21 plants it is treated with hypochlorite. The municipally owned plants number 396. As to rates, where specified, it is shown that flat rates are used in 209 cases, meters in 30, and both flat and meter in 141. There are 279 sewerage systems in Canada, having an aggregate mileage of 4,223 and which have been built at a total cost of \$74,504,418. In only 75 municipalities is the sewage treated.

**FOR SALE—SCREW-CUTTING LATHE, 14 FT.** bed, 16-inch Imperial chuck, 24-inch Swing Countershaft. Apply Thos. H. Ruth, 314 Pearl Ave., Peterboro. (1)

**FOR SALE—ONE DAVIS 4½" CUTTING-OFF** machine; practically new; been used less than three months; very reasonable. Canadian Linderman Co., Ltd., Woodstock, Ont. (1f)

**12-INCH HEAVY DUTY (CANADIAN CORPORATION)** moulder; just used six months; also band saw, shaper, buzz planer, used two years. Apply W. A. Rumney, 36 Fuller Ave., Toronto. (28)

**20,000 LBS. ½ GALVANIZED STEEL GUY** wire. We can offer this wire at very attractive prices. Winnipeg Machinery Exchange, Sutherland and Gladstone Sts., Winnipeg, Man. (25)

**1—2-SPINDLE SHAPER, WOOD TOP, JOHN** Ballantyne, Preston, make. used two months. 1 Dynamo, 45 lights, Toronto and Hamilton Electric Co. make. Used five months. Good as new. Box 195, Jordon, Ont. (R.T.F.)

**DROP PRESS FOR SALE—NO. 9 MINER & PECK** drop press; anvil 2,000 lbs.; base 30,000 lbs.; 36" between uprights; 40" x 35" between poppets; 34" x 29" top of anvil; guaranteed as good as new. Can be shown in operation to any genuine prospective buyer. The Metallic Roofing Co., Limited, Toronto. (4)

**FOR SALE — THREE HOLDEN-MORGAN** threading millers; one arranged for nose threading; two for base threading. One base threader can be changed to 4.5, as it was reduced from this size. Also two Bertram wavers and groovers, and one Martin, all used for 3.3 shells. Canadian Linderman Co., Ltd., Woodstock, Ont. (27)

## FOR SALE

**Fox Monitor Lathe, 18" x 5' 6",** 9-hole turret, cross feed, hollow spindle, 5-step cone; good as new. Plating dynamo, 6 volts, 250 amp.; used only a short time.

**PENDRITH MACHINERY COMPANY**  
970 Queen St. West, Toronto

**FOR SALE—5 CARLOADS MACHINERY** steel, consisting of rounds from ¼" to 5", squares, flats, angles and channels. Also tire sections. Slightly rusted through being outside. Will move this entire stock at great sacrifice in price to someone who can take delivery of entire quantity at once. This is an exceptional offer. Box 210, Canadian Machinery. (1)

**FOR SALE—NEW HAVEN, 60-INCH SWING** Standard Engine Lathe—triple geared, 15 ft. bed, hollow spindle, cuts threads 1 to 12. Compound rest, countershaft, steady rest, wrenches, etc. This tool is in excellent shape and owner offers special bargain. Particulars from Winnipeg Machinery Exchange, Sutherland and Gladstone Streets, Winnipeg, Man. (24)

**FOR SALE — AT ALEXANDRIA, ONT. —** Machine shop in two buildings; 10,500 sq. feet concrete floor space; equipped with lathes, shaper, planer, miller and variety of other iron-working machines and tools; good foundry in connection. Inventory of buildings, machinery and stock, \$64,272. Practically new plant; in good condition. F. T. Costello, Assignee, Schell F. & M. Co., Ltd., Alexandria, Ont.

**FOR SALE—McDOUGALL ENGINE LATHE** 20" swing, 10' bed, complete with 20" 4-jaw chuck, countershaft, steady rest, face plate, gears, etc. This tool, we understand, has never been used; has been lying crated for about 5 years. We are having it cleaned and offer a decided bargain for quick sale. Winnipeg Machinery Exchange, Sutherland and Gladstone Sts., Winnipeg. (3)

## SITUATIONS WANTED

**MECHANICAL AND ELECTRICAL ENGINEER,** 16 years' experience, plant layout and maintenance; expert draftsman; wishes change. Box 207, Canadian Machinery. (26)

**POSITION WANTED AS SALESMAN,** agent, or traveler, for mechanical goods, or machinery, by Chief Engineer, (Marine), thoroughly reliable, of good education and appearance. Box 209, Canadian Machinery. (3)

**MECHANICAL ENGINEER OPEN FOR POSITION** of shop superintendent. Wide experience in mining machinery and electric motors, hot water boilers and radiation. Experienced in tool-making, designer, and a keen cost observer. Has had seven years' foundry experience, familiar with moulding machines and a post-graduate of McLain's system of mixing iron. Familiar with shell work. Can give the best of references. Box 211 Canadian Machinery (4)

## REPAIRING

**ALL KINDS OF MACHINERY REPAIRED,** rebuilt and installed. W. H. Sumbling Machinery Co., 643 Yonge Street, Toronto, Ont.

## WANTED

**Burned out Tungsten Lamps,** late type, drawn wire. 25, 40, 60 and 100 Watts, 110 and 115 volts.

**DOMINION TUNGSTEN  
AMP FACTORY**  
ST. CATHARINES, ONTARIO

## WANTED

**WANTED—ELECTRIC TRAVELLING GANTRY** crane, span about 57 ft., clearance 50 ft., overhanging at one end; load 15 tons. State full particulars and price. Thor Iron Works, Limited, Toronto, Ont. (27)

## Wanted to buy or sell Scrap Iron, Metals, etc.

At the present time we are paying the following prices:

No. 1 Scrap Wrought Iron, \$13.75 gross ton.  
Heavy Scrap Copper, \$20.00 per cwt.  
Mixed Heavy Scrap Brass, \$13.00 per cwt.  
Heavy Scrap Lead, \$5.75 per cwt.  
Scrap Aluminum, \$32.00 per cwt.  
Scrap Babbitt, \$3.00 per cwt.

Our Motto: Honest dealings and prompt settlements. Make us a trial shipment.

**L. S. TARSHIS & SON**  
88-98 Wellington Street, Montreal

## Lathes for Sale Second Hand CHEAP

**One Prybil Spinning Lathe No. L7.** 6-foot Bed with screw control gap. Complete attachments.

**Good as New. Price \$450.**

**One Windsor Machine Co. No. 4** Turret Lathe.

Six-hole turret hollow spindle take two-inch stock. Partly fitted with chaser bar attachments, screw adjustments and quantity of draw chucks.

**A Real Bargain at \$350.**

Write for further particulars to

**ONTARIO LANTERN &  
LAMP CO., LTD.**

FIG. 1. PART OF MACHINE SHOP, SHOWING TYPES OF MACHINES ENGAGED IN FINISHING DETAIL PARTS OF BALL-BEARINGS.

## Ball Bearing Manufacture in a Specialized Canadian Plant

Staff Article

*Conservation of energy through elimination of transmission losses is receiving increased attention from the engineers of to-day. It is rather anomalous, however, that hitherto the largest, most obvious, and most easily remedied of factory losses has been overlooked in efforts to perfect systems as a whole rather than improve familiar details in everyday use. The adoption of ball-bearings for line shaft work indicates the advance in general practice, the product dealt with here playing a large part in the inception of the ball-bearing era in Canada.*

**B**ALL bearings as a power-saving feature in transmission apparatus are an accepted fact in modern engineering circles. All progressive engineers are familiar with the evolution of the ball-bearing from the crude unreliable devices of the pioneer bicycle days to the product of highly specialized factories. With ever-rising costs of production in labor and material, manufacturers have, during recent years, been compelled to consider every possible means of obtaining economy, with the result that power transmission losses are now subject to continuous investigation in practically all lines of manufacturing.

Established in this country in 1902, the Chapman Double Ball Bearing Co. was formed to develop patents granted to C. A. Chapman, and since then have been continuously engaged in the production of various types of ball bearings for power transmission equipment, and special and general machinery. As now produced by the firm, Chapman ball bearings are

unique in respect of the fact that they are made in the only factory of its kind in Canada. Their design and manufacture are based on the experience gained in equipping over 2,000 factories which has resulted in the entire elimination of any undesirable features, which may have existed in the original design years ago, and the evolution of an item of transmission equipment capable of meeting all demands so far as service is concerned, while effecting economies unobtainable with

equipment of a conventional design.

### Constructional Features.

The Chapman ball bearing as adapted for the majority of general shafting work is of the cup and cone type, two double opposed ball assemblies being mounted in the ends of a cast iron housing. The details of construction are clearly shown in the sectional line drawing Fig. 2, while the external appearance of the bearing mounted in an ordinary shafting hanger is shown in Fig. 3.

A consideration of the features exhibited in these illustrations brings out two salient facts concerning this design of bearing—first, by using two sets of ball races in the manner shown, the dimensions of the housing are retained within limits which make the bearing completely interchangeable with existing self-oiling boxes of the same shaft sizes in any standard type of hanger frame; second, as a result of the first feature there is practically no limit to the size of ball or diameter of ball race

FIG. 2. SECTIONAL DRAWING OF BALL-BEARING SHOWING DETAILS CONSTRUCTION.

lution of an item of transmission equipment capable of meeting all demands so far as service is concerned, while effecting economies unobtainable with

dard type of hanger frame; second, as a result of the first feature there is practically no limit to the size of ball or diameter of ball race

which can be incorporated in any one size of bearing. Due to the latter fact, therefore, these bearings possess an exceedingly high carrying capacity largely in excess of any load which the corresponding size of shaft would be able to sustain continuously. Under all ordinary factory conditions, therefore, the

FIG. 3. STANDARD TYPE OF SHAFTING BEARING IN HANGER FRAME.

factor of safety is more than ample to insure a very long period of service.

#### Large Balls Used.

Referring to Fig. 2, it will be seen that the two bearing units are composed of balls having a diameter approximately equal to one-third of the shaft diameter, the inner raceways or cones being so disposed in relation to the outer raceways or cups that the angle of ball contact is inclined inwardly at each end at an angle of 15 degrees, thus permitting a suitable percentage of thrust load in addition to the radial load. The main casting or housing B, which is held stationary in the hanger frame, is of cast iron, suitably proportioned to withstand stresses, and having its ends accurately machined to receive the cups or raceways L. These cups and the cones or inner raceways M, are of a special grade of steel, formed into shape in power presses and then heat treated so as to impart to the metal the degree of hardness which is necessary for the proper performance of its duty.

The inner or revolving unit of the bearing consists of a seamless steel sleeve E, which is secured in position on the shaft by means of split tapered bushings or sleeve wedges G, which fit into corresponding tapers formed in the ends of the sleeve.

#### Method of Fastening on Shaft

The pressure of the balls on the cone is distributed around the sleeve by the cone wedge H, these three pieces being assembled under pressure so as to give a body of solid metal between the balls

and the shaft. This construction enables the cones to be accurately adjusted toward each other in order to eliminate play in the ball races, after which lock nuts J are tightened up on the threaded ends of sleeve and secured permanently in position by a rivet, the inner end of which has a square head which engages with the split in the sleeve wedge. The object of this becomes apparent when the manner of tightening the sleeve wedge is considered. The outside of lock nut J has a right hand thread, the outside of sleeve wedge G has a left hand thread, and the adjusting nut I has corresponding right and left hand threads so that when turned in a right hand direction, looking on the end of the bearing, the opposed threads cause the sleeve wedge to enter the tapered ends of the sleeve thus contracting the wedge which grips the shaft firmly without damage. The square rivet head prevents the sleeve wedge from turning on the shaft when the lock nut is being tightened.

By means of this method of fastening the bearing can be installed on shafting varying from .005 in. oversize to .005 in. undersize. Grease retainers insure the proper application of lubricant over extended periods while an efficient type of dust cap prevents the access of dust or grit under adverse conditions of working.

TABLE OF MAXIMUM LOADS.

Size of Bearings.	REVOLUTIONS PER MINUTE.											
	100	150	200	250	300	350	400	500	600	700	800	1000
	MAXIMUM LOADS FOR THE ABOVE SPEEDS.											
1	2720	2400	2160	2000	1840	1700	1680	1600	1480	1400	1360	1280
1½	3200	2800	2480	2320	2160	2080	2000	1840	1760	1680	1600	
2	4560	4000	3640	3360	3120	2960	2880	2720	2520	2400		
2½	6400	5680	5200	4800	4520	4280	4080	3800	3600			
3	8160	7120	6480	6000	5680	5360	5120	4800				
3½	10880	9520	8640	8000	7520	7200						

NOTE.—The loads cited above are for steady speeds and constant loads, evenly distributed on the bearings. Where the load is on one end of the bearing, only one-half of the above loads are permissible.

#### Capacity of Standard Sizes.

As indicating the carrying capacity of these bearings the above table gives the maximum loads for standard

FIG. 4. BALL-BEARING PILLOW BLOCK WITH SELF-ALIGNING BALL AND SOCKET CONSTRUCTION.

sizes of the cup and cone type at different speeds, while heavy duty bearings are also produced in which each size of

bearing is suited for the load of the next bigger size of regular bearing.

The Chapman type of ball bearing construction has been developed so as to include pillow blocks and loose pulley bushings. A pillow block of the ball and socket type is shown in Fig 4, which, while taking care of either misalignment or spring shafts, has a very short distance between the base and the centre which permits its use in many situations

FIG. 5. BALL-BEARING BUSHING FOR LOOSE PULLEY.

where the ordinary adjustable pillow block could not be used.

#### Pulley and Clutch Applications.

Fig. 5, shows the interior arrangement of a loose pulley bearing or bushing, which has proven satisfactory in overcoming inherent troubles of ordinary loose pulleys. In addition to saving time and trouble through heating due to neglect or overload, these pulleys ef-

fect substantial economies in lubrication and necessary attention. The lubricant used is a high grade vaseline which does not leak like oil or get thrown around, increasing fire risks or damaging goods, and as the sleeve in contact with the shaft does not revolve there is no wear on the shaft with consequent depreciation. Clutch sleeves are a kindred item of power transmission equipment which have been also standardized in ball bearing types, the sleeve in this case being secured to the shaft with wedges in the same way as the shaft bearing.

The light shafting bearing shown in Fig. 6, is an interesting example of pressed steel manufacture, the cups, coned sleeve, housing and cages being low carbon steel stamping hardened and ground on all wearing surfaces. The size of shaft for which this bearing is made, 1 3-16 in. renders it particularly adapt-

ed for factories having small powered groups of machines, while quite apart from the power reduction, the cleanliness and freedom from attention are conspicuous features. The manner of installing this bearing is shown in Fig. 7 and 7a, where power table hangers of both two and three point support are illustrated. Suitable indentations are made on the housing to receive the points of the supporting screws.

That the successful application of ball bearings is not confined to small or ordinary sized shafts will be gathered from the photo

FIG. 6. LIGHT SHAFTING BEARING OF PRESSED STEEL CONSTRUCTION.

of a main drive in a Canadian cotton mill where heavy duty bearings have transmitted 300 horse-power for five years with complete freedom from trouble of any kind. The smaller bearings on the right have been in service for nine years.

#### Manufacturing Features.

As will be understood by practical readers, the production of work of this nature calls for a high degree of skill, uniform material of a high grade, and accurate machinery. The production of

steel stampings for ball cages, cups, cones, etc., is done in power-driven presses, one of which is capable of exerting a maximum pressure of 600 tons, another one 200 tons, while a number of small quick acting presses are employed on grease retainers and ball cage stampings.

The making of a ball cage is an interesting part of the press work and the various stages of a cage in the course of manufacture are shown in Fig. 10, each piece being numbered in rotation from the blank to the cage with assembled balls. No. 1 is punch-

FIG. 7. TYPE OF HANGER FRAME OR FLOOR STAND FOR LIGHT SHAFTING BEARINGS.

FIG. 7A. TYPE OF HANGER FRAME OR FLOOR STAND FOR LIGHT SHAFTING BEARINGS.

FIG. 8. MAIN DRIVE SHAFTING RUNNING ON BALL-BEARINGS AND TRANSMITTING OVER 300 HORSE-POWER IN A COTTON MILL.

ed from a flat strip of highly finished cold rolled steel. No. 2 is the blank formed to shape with

at the other end so that the cups are centred from the rough interior, while they are rapidly and accurately ground

points of contact between the balls and raceways will be approximately 15 degrees from a vertical line at right angles to the shaft.

Accurate and economical grinding of this curve is accomplished in a Landis radius grinder shown in Fig. 11, and observable in the foreground of the view of grinding department, Fig. 12. The cup is held in an adapter on the oscillating head A, which is swung back and forth automatically, while the internal grinding wheel is adjusted longitudinally by the hand-wheel B in the operator's right hand and transversely by the feed wheel C on the upper part of the wheel slide.

The grinding of the cone is done in the reverse order, being located by the

FIG. 9. GROUP OF LINE SHAFTING BEARINGS FROM 1 IN. TO 6 1/2 IN. DIA. OF SHAFT.

spherical depressions to receive the balls and spaces between the balls to contain the spacers which retain the balls in position. No. 3 is the formed blank trimmed on the outside, and No. 4 is the same trimmed on the inside, either of these two operations being performed first. As shown in No. 5, the part is completely finished ready for assembling with another exactly the same. This is done by means of electric welding, the small surfaces just outside of the spacers being clamped between the points of a spot welder which fuses the two surfaces together inseparably. After being cleaned and thoroughly inspected, the balls are inserted in the pockets formed between the two stampings, as in No. 6, when the cage is ready for assembling in one end of the housing.

#### Grinding the Ball Races.

In grinding the cups, they are mounted in batches on a mandrel, being supported and located by formed discs which are slipped on the mandrel between the cups, all of which face the one way. With ten or twelve cups on the mandrel, a nut at one end tightens both cups and discs against a shoulder

to size on the outside. The interior curve of the race has to be of an exact radius and diameter so that when assembled with the balls and cone, the

FIG. 12. GENERAL VIEW OF GRINDING DEPARTMENT, WHERE CUPS AND CONES ARE ACCURATELY GROUND TO SHAPE.

FIG. 10. STAMPED PARTS OF PRESSED STEEL BALL CAGE IN PROCESS OF MANUFACTURE.

outer curved surface, resting in a hollow adapter while the tapered bore is ground to gauge. This operation is then followed by placing the cone on a tapered arbor and grinding the ball track with a formed wheel trimmed to the correct radius. The ground surfaces of the raceways are now polished to a mirror surface, the degree of finish obtained having considerable influence on the length of life of the bearing before wear begins to affect it.

#### Machine Work and Testing.

The various details referred to in Fig. 2, are produced on machinery of the most modern type, part of the machine shop being shown in Fig. 1. Among the various machines may be noted heavy turret lathes by Pratt & Whitney, Steinle, Acme, and Libby engaged on housing and the larger parts, while Jones & Lamson lathes are occupied with sleeve wedges, adjusting nuts

and similar threaded parts. Three 60 in. Colburn boring mills enable large thrust bearings and special castings to be handled to advantage, one of these being fitted with a special grinding head for grinding ball races up to 36 in. diameter.

The assembly and testing department is shown in Fig. 13. Here the various units are tested individually before being finally assembled and shipped out. In the left foreground may be observed several stacks of ball cages, on the floor are wooden loose pulleys with ball bearing bushings also a group of clutch sleeves, while to the right are two testing stands with bearings under test. These stands each consist of two heavy frames carrying bearings of the size to be tested. On the shaft passing through these two bearings are mounted other two bearings which are subjected to load by hydraulic pressure from below. A certain scale of pressures and duration of tests is adhered to for the various sizes of bearings in excess of anything likely to be met with in practice. On the conclusion of the test each bearing is dismantled, when each individual ball and wearing part is scrupulously inspected for any developed flaws.

The balls, along with the raceways, are the vital parts of the bearing and upon the accuracy and quality of material depends the entire success of the ball bearing industry. Great advances in ball manufacture have been made in recent years, and the balls used in these bearings are accurate within a limit of 1-10,000th part of an inch both as regards sphericity of each individual ball, and uniformity in size. The balls are made of special alloy steel, being forg-

FIG. 13. ASSEMBLING DEPARTMENT, WHERE COMPONENT PARTS ARE TESTED

ed, rough ground, finish ground and finally polished to a mirror finish. The successful production of high grade balls in large quantities at a reasonable cost has contributed greatly to the increased use of ball bearings in many industries, and in conjunction with correct design and careful manufacture assure the permanent status of ball bearings as indispensable items in many branches of the world's industries.

#### ENORMOUS ADVANCES IN CANADIAN TRADE.

ANOTHER record-breaking trade statement was issued on July 25 by the Department of Trade and Commerce, Ottawa. It shows an increase of more than

93 per cent. in the grand total of Canadian trade for three months of the fiscal year ending June 30. The volume of trade on that date had reached the imposing figure of \$527,512,344, as against \$272,646,868 for the first quarter of 1915. The increase has been pretty evenly divided as between the two branches of trade, the imports having risen from \$98,017,187 to \$186,245,480, and the exports from \$113,578,221 to \$245,381,035.

Foreign exports increased from \$8,577,775 to \$66,989,732, a jump which seems to be accounted for under metals, the exports of foreign mine products increasing in the three months from slightly less than two millions to sixty-two millions and a half. These exports in the month of June alone rose from \$8,138 to \$51,886,013.

The June trade contributed largely to the good showing for the financial quarter, the increase in the trade total being from \$127,402,516 in June, 1915, to \$243,953,544 in June of this year. Domestic imports increased from \$35,324,739, to \$66,399,838. Although the larger proportion of increase is shown under free goods, which jumped more than 100 per cent., there is a substantial increase shown in the amount of duty collected for the month. The total Customs receipts were \$12,105,268 as against \$7,409,238.

The exports for the month show very heavy increases in manufactures, in agricultural and in mineral products. From the mines the exports rose from \$4,649,014 to \$7,755,875, agricultural products from \$14,269,748 to \$38,744,527, and manufactures from \$9,757,146 to \$32,252,447.

Halifax, N. S.—The Nova Scotia Car Works were sold on July 26, to F. B. McCurdy, M. P., for \$167,500.

# Data Relative to Foreign Trade, Commerce and Transport

Compiled and Selected

*Whether with a view to the prosecution of inter-Empire trade, or that with neutral or Ally countries on conclusion of the war, it is necessary that information of the most diversified and reliable nature be available. In this section it is endeavored to meet the latter need, while at the same time abstaining from all attempt to advise as to a course of action.*

## DEVELOPMENT OF ANGLO-RUSSIAN TRADE

THE following article from The Times Russian Supplement of April, 1916, should be of unusual interest to Canadians, showing as it does the preparations that have to be made in Great Britain, and which will have to be made in Canada preliminary to the development of Russian trade.

### Development of German Trade

The remarkable development of Germany's commercial connections with Russia is due to many causes. The two countries, in the first place, are contiguous, which implies that numbers of Germany's citizens are reared in close proximity to the frontier, and therefore gain a practical knowledge of the Russian language in early life; this, for German commerce, removes the language difficulty. Moreover, the number of Germans resident in Russia is enormous—some localities are said, indeed, to contain more Germans than Russians, and these assist considerably, both by natural inclination and by reason of their knowledge of Germany and its industries, in fostering German trade with Russia. These circumstances, again, render comparatively simple the acquisition of a fundamental knowledge of Russian requirements and of the Russian markets, the conditions of which differ markedly from those of the rest of the world. Undoubtedly, the result is also consequent upon the thoroughness of German methods and the capacity for taking pains, qualifications which, however, are not a monopoly of the Teutonic race.

### German Banks

Any of the foregoing advantages which Germany possesses, however, appear to be of minor importance compared with the aid given to German commerce by the banks. It is customary to talk of German "commercial" banks, but in practice banks there of the highest standing, the Deutsche Bank and the Dresdener Bank included, participate largely in this description of finance. Such participation may be roughly divided into direct and indirect. On the one hand, the German banks themselves directly own debentures or stock in industrial concerns both in Germany and elsewhere, or have a direct interest in syndicates controlling industrial concerns; on the other hand, they discount commercial paper freely and make ad-

vances to commercial and industrial houses, without raising difficulties, both for general purposes and against specific orders. German banks also, as is well known, have substantial holdings in Russian banks—another important factor in enabling the former to gain accurate knowledge of the standing of Russian firms to whom credit is given.

### Long Credit

The importance of these operations of German banks, as regards Russia, is principally due to the fact that long credit must be given in that country. Whilst four to six months is usual in many branches of trade, it is by no means uncommon for credit to be granted, for certain articles, up to two and even two and a half years; though, be it added, losses on account of bad debts may, with ordinary care, be limited to an amount which will not prejudice the business. Clearly, the capital required to enter into such a market is out of all proportion to that which is needed in most of the larger countries where a comparatively speedy turnover may be expected; a Canadian house, capitalized on the basis of the customary requirements of this country, obviously has little spare capital wherewith to compete in Russia.

The question is pertinently asked how does it come about that Germany is capable of investing such enormous amounts in, and providing such large sums for, commercial and industrial enterprise both in Germany itself, in Russia, and elsewhere. The question leads to a further aspect of the pre-war situation which will be realized with very mixed feelings by the Canadian manufacturer and merchant. The position is largely summarized thus:—

The German merchant draws a bill, which his bank discounts: the bill goes to the London money market, where bearing as it does the endorsement of a German bank, it is sold as good paper. Thus it happens that the great London financial institutions, whilst looking askance at the commercial methods of those in Germany, provide the funds where-with, in large measure, Germany industry is so generously supplied. The branches of the German banks in London appear to be established solely for the purpose of facilitating transactions of this nature, and thus extending the practice of borrowing British capital to further German commerce.

### Position of British Banks

Why do not British banks employ a substantial portion of their funds similarly for developing British commerce? Briefly, they contend that it is not the function of a bank to take a direct share in industrial enterprises, and that a bank is not justified, in the interests of its depositors, in assuming the risks which such participation involves; that the wonderfully strong position of the leading British banks, unshaken by the tremendous upheaval caused by the war, is primarily due to the soundness of their system, whereas the financial position in Germany, where wider methods are employed, has long been open to question. London bankers, it is a matter of common knowledge, have expressed the opinion that a great financial crisis, affecting Germany, would amply justify their attitude, and it yet remains to be seen whether this view is correct.

The fact remains that Germany, by her financial manoeuvres, has reaped incredibly remunerative harvests in Russia, and has built up an enormous trade between the two countries; of this Great Britain and Canada must, by some means, obtain an increasing share. The relations between Russia and British banks must become more intimate in order to allow of greater assistance, discounting facilities, etc., being granted here. Already a number of Russian banks have opened offices in London, whilst the last decade has witnessed the organization of several Anglo-Russian banks. A commencement can, therefore, be made with a system by which, through the intermediary of Russian banks and their branches in the Russian provinces, British money may be employed in British, instead of German trade. It has been stated that German banks have special intelligence staffs to supervise the industries in which they are interested, and that they retain the services of leading experts—scientific, engineering, etc.—to advise on technical questions: by such means the risk involved in supporting commercial and manufacturing ventures is minimized.

### Credit Bank Organization

If, in spite of what is now known of German methods, British banks refuse to follow the lead to any considerable extent, there is a further means of securing the desired result, i.e., the organization of commercial or credit banks. In this suggestion is to be found, in the opinion of the committee, the true

solution of the problem; it is one in which, as now appears, the joint-stock banks would be willing to participate indirectly. Even so, however, Government assistance in the way of guarantees or otherwise, will probably be a *sine qua non*, at any rate, at the outset. Apparently this was also the case in Germany.

#### After-war Conditions

It should be emphasized that the position must be rectified now, in readiness for normal conditions. For, whilst the animus created by the war will be, to a large extent, effective when international relations are resumed, it is idle to assume that Germany's trade with Russia must become a thing of the past. The Russian will find that he must provide at the lowest cost for the requirements of his customers, and the actual consumer is rarely in a position to know whether or not he is supplied with a German article. Further, Russia must have credit, will, indeed, require it more than ever after the present war, and if Great Britain fails to rise to the occasion, must seek other means of obtaining it. The war has afforded an extraordinary opportunity for British houses, aided by British financiers, to gain possession of a far greater share of Russian trade, but the initial steps must be taken at once, otherwise the opportunity will be gone, and it is unlikely to recur for another generation.

#### Alleged British Failings

While the question of credit is of the first importance, there are other aspects of the situation which require mention. Complaints are frequently made that the British manufacturer and the British merchant display an entire lack of energy initiative, and cling tenaciously to methods long superseded and, particularly, to the desire to force their products upon the foreigner rather than to produce in the first place the article which the foreigner demands. No doubt, broadly speaking, there are still considerable grounds for this accusation, but the committee incline to the view that the comparative impossibility in most branches of trade of obtaining any considerable hold upon the Russian market, owing principally to the credit difficulty, provides the real explanation of this attitude. In other words, the British manufacturer will not lay out capital where the possibility of any substantial success is problematical. There are, of course, minor reasons which merit attention, such, for example, as the difficulty of securing travellers and representatives who speak the Russian language, are conversant with the conditions of the Russian market, and who, at the same time, know the articles in which they deal. As already stated, these difficulties have been largely smoothed

away by circumstances for the German firm.

The accusation frequently made that British firms often quote f.o.b. in English currency and forward to Russia catalogues in the English language and employing English prices, weights, and measures, whereas the German firm quotes in Russian currency, duty free, delivered on the spot, is undoubtedly true; the reports of the British Consuls in Russia provide conclusive evidence of this. In extenuation, however, it may be pointed out that the preparation of catalogues and price lists in Russian, an expensive process, is often not warranted by reason of the fact that, owing to the circumstances alluded to above, no great turnover is to be expected. The point should in spite of this be carefully considered.

Reference has been made to the language difficulty. Clearly time will be required to alleviate to any appreciable extent the existing situation. Education authorities are now, however, giving earnest attention to the matter, as is evidenced by correspondence which has recently passed between the Chamber and the Chief Education Officer of the London County Council, to whom the views of a number of members have been communicated. The teaching of Russian in England will, however, not wholly solve the problem; it is essential that young Englishmen should go to Russia to gain the required facility in the use of the language, a course which would at the same time afford opportunities of gaining a practical insight into Russian methods and requirements, and thereby acquiring much information which can only be obtained on the spot. No doubt the education authorities of the two countries could devise an interchangeable scheme which would go far towards effecting the desired result.

#### Fiscal Conditions

It will have been noted that no mention has been made in the foregoing report of fiscal conditions, the principal reason being that, up to the outbreak of the war, Great Britain and Germany were, as regards duties, on much the same basis, though it should be stated that the Russo-British Treaty of Commerce and Navigation (1859), except in so far as it confers upon Great Britain most-favored-nation treatment, is out of date and should be revised. Obviously Germany's commercial success in Russia was not due to any special advantages of this nature. It may safely be assumed that after the war Germany will be at a disadvantage, for the economic conference of the Allies in Paris is, as all hope, the first step towards an economic entente, the effect of which will demonstrate Germany's deplorable error of judgment in endeavoring to acceler-

ate her peaceful penetration by the assumption of military domination.

#### Statistics

The following figures show the extent of Anglo-Russian commercial exchanges during the last few years and the principal articles of which they are composed:—

(a)—Imports into the U. K. from Russia.

1910	£43,644,648
1911	43,154,411
1912	40,538,532
1913	40,270,539
1914	28,092,527
1915	21,429,333

(b)—Exports from the U. K. to Russia (including re-exports).

1910	£21,220,727
1911	22,316,679
1912	21,741,486
1913	21,792,186
1915	25,447,780

(c)—Principal articles exported to Russia from the United Kingdom, British produce or manufactures (in approximate order of importance):—Coal, machinery, fish (herrings), iron and steel and iron and steel goods, woollen yarn and woollen goods, cotton yarn and cotton goods, ships and boats, raw wool, tin implements and tools, machine belting (these goods represent 80 per cent. of the total). Re-exports of colonial and foreign merchandise:—Raw cotton, rubber, unrefined tallow, oilseeds and nuts, machinery and tea.

(d)—Principal articles imported from Russia into the United Kingdom:—Wood and timber, corn and grain, eggs, butter, flax and tow (these goods represent 60 per cent. of the total).

#### Some Recent Statistics

M. Alexander Bashmakov, of the Russian Official Messenger, who was one of the party of Russian journalists recently in England, has prepared a memorandum on the subject of Anglo-Russian trade. From this we take the following extracts:—

Russian trade has doubled in the last twenty years, the main growth being in the last five years. Exports for 1914 have fallen by 564,000,000 roubles (37 per cent.) and imports by 276,000,000 roubles (20 per cent. of the former year). The following are the figures:—

	Value
Imports.	(Roubles).
1913	1,374,000,000
1914	1,098,000,000
Exports.	
1913	1,520,000,000
1914	956,000,000

The share of different countries in Russian imports is as follows:—

	Millions of Roubles.	
Country—	1913.	1914.
Germany	652	429
Great Britain	173	171

United States ....	79	80
China .....	84	89
Japan .....	4	12
Egypt .....	5	7

The shares of Germany, France, and Great Britain in the trade of the country is shown by the following percentages of value:—

	Imports, 1913. Per cent.	Exports, 1913. Per cent.
Germany .....	47	29
France .....	4	6.6
Great Britain ...	12.6	17.6
Holland .....	—	11.7

Thus of a total value of Russian trade in 1913 of 2,894,100,000 roubles the share of Germany was 1,105,800,000 roubles, divided between imports 652,200,000 roubles and exports 543,600,000 roubles. These figures are taken from the Official Report of the Russian Department of Customs.

The total capital invested in industrial companies in Russia is (according to the Official Report of the "Imperial Board of Trade and Industry," 1914) 3,964,126,000 roubles, distributed as follows: (a)—Russian Societies, 3,376,780,000 roubles; (b)—Foreign Societies, 587,346,000 roubles. Foreign companies, represent 14 per cent. of the total value.

British companies which have been established in Russia have a capital value of 156,581,000 roubles, while German companies have apparently only 67,969,000 roubles. At first sight, therefore, it would seem that British capital in Russian industry is about 4 per cent. of the total value (or 26 per cent. of the foreign capital), whilst German capital is only 2 per cent. of the total value (or 11 per cent. of the foreign capital); but this is really not so.

It is beyond doubt that about fifteen very big undertakings registered as "Russian" and having a capital amounting to 110,575,000 roubles, are in reality German companies, though designated as "Russian" undertakings, and, therefore, the true sum of German capital employed in Russian industry would be at least 178,544,000 roubles—that is to say, more than 4 per cent. of the total value (or 30 per cent. of the foreign capital).

#### Principal German Industries

Whilst British capital is invested only in some special undertakings, such as mines and, above all, in the petroleum industry, goldfields, and copper mining, the Germans are established in the machine, electrical, chemical, and metallic industries, as is shown by the following

Industry.	German Companies. Capital (rbls.)	British Companies. Capital (rbls.)
Electrical machinery ..	113,289,000	2,552,000
Chemical materials ....	24,900,000	.....
Wood and timber .....	13,380,000	.....
Metallic wares .....	13,658,000	.....
Coal mines .....	10,595,000	11,353,000
Copper mines, gold and emeralds .....	.....	43,463,000
Petroleum .....	.....	95,010,000
Total of principal in- dustries .....	175,811,000	152,377,000

The power of German capital in Russian industry is really much greater than these figures show, for two reasons: First, because Germany has control of so many of the industries concerned with the most useful and necessary products for human existence; and, secondly, because, as shown above, many companies, apparently Russian, are in reality of German origin and ownership.

#### THE COMBINED RAILWAY AND STEAMER BILL OF LADING

OF all the objectionable shipping documents transmitted to Australian importers by Canadian exporters of goods and products, the "Combined Railway and Steamer Bill of Lading" easily takes first place. Prior to the war, the use of such documents was not general, but in recent months it has been the rule rather than the exception. So grievous is the discontent amongst importers of Made-in-Canada goods that representations have been made to the effect that the Canadian Government should be approached with the view of enacting legislation to make it an offence for the railways in the Dominion to issue a document so detrimental to the material interests of manufacturers and exporters, as the combined bill of lading.

The assumption is that manufacturers in Canada, especially those distant from the seaboard, are unaware of the serious reflection upon their lack of knowledge of oversea trade requirements by attaching a wholly incomplete bill of lading to their drafts upon Australian buyers, or covering purchases made under a letter of credit established in a Canadian bank. An occasional transaction of such character might be overlooked, but so common has the practice become that Australian merchants are refusing to accept drafts accompanied by the combined bill of lading, and Australian banks are instructing their respective agents in Canada not to negotiate drafts drawn against established credits unless they are supported by a clean steamer bill of lading.

#### Objection of Merchants

Some of the leading importers of Canadian goods and products have refused to accept or pay drafts supported by a combined railway and steamer bill of lading, as they claim that it is not a negotiable document because it absolutely gives no assurance when the goods will come to hand. Further, it is not a receipt from the steamship company, and the various lines invoiced may come forward in several steamers, thus entailing endless annoyance and trouble at the port of discharge.

In the case of iron and steel products shipped in bars or bundles, the combined bills of lading are endorsed by the railway company "shippers' load and count more or less," which gives the Aus-

tralian consignee no grounds against the steamer for redress for any material short landed, as the shipping agents contend that such an endorsement frees them from any claim for the missing products. This combined bill of lading gives no guarantee whatever that the goods will ever be shipped intact from the seaboard.

On a copy of a combined bill of lading forwarded with this report, it was shown that 57,750 pounds of Canadian bar iron were shipped from an inland town, consigned to Melbourne, but if the purchasers receive only 50,000 pounds, or even less, they have no grounds for action in claiming upon the shipping company on account of the endorsement "shippers' load and count more or less."

#### Objection of Australian Banks

The opinion of a leading Melbourne banker upon the objection to the combined railway and steamer bill of lading was obtained, and is submitted for the information of Canadian banks, manufacturers and exporters:—"From a banker's point of view, the objection to the document is that it is not a legal security in Australia. The courts both in England and throughout the Commonwealth rule that a bill of lading is a valid instrument only when the goods are actually shipped. A bill of lading which does not show the name of the steamer is not a valid instrument, and is, therefore, not a legal security. In Australia, even though the name of the steamer be inserted, the document is not necessarily binding on a shipping company unless that particular steamer is in port at the time of date of issue of the bill of lading. My objections are as under:—

1.—A banker negotiating a draft supported by such a document has no tangible security.

2.—He runs the risk of the drawee in Australia declining to pay until arrival of the relative goods.

3.—No remedy is in the hands of the banker for goods short-shipped, and experience up to date shows that in connection with combined railway and steamer bills of lading irregularities in shipment have been almost chronic.

"It appears to me that an easy solution of the whole trouble could be achieved by the negotiating bank of Canada either declining to negotiate the draft until the goods were actually shipped, or offering to negotiate the draft on condition that interest during the period of delay between the date of negotiation and date of actual shipment should be paid by either the shipper in Canada or the consignee in Australia, or perhaps divide the interest equally between the two; but it should be a sine qua non that the draft must be retained by the negotiating bank in Canada until actual date of shipment is assured."—T. & C. Bulletin.

# Review of the Timber Resources of British Columbia

*Among Canada's natural resources, her forest territory occupies the very front rank. These great timber areas located all the way from the Atlantic to the Pacific, are, however, neither as fully comprehended by ourselves nor by buyers abroad as they might be, whether in the light of their vastness or of their money value. Through the courtesy of the British Exporter and the B.C. Lumber Commissioner, at Toronto, we are enabled to put before our readers data and illustrations relative to the timber resources of British Columbia, and in so doing, hazard the opinion that considerable enlightenment will accrue from their study.*

ONE result of the war is that increased attention is being directed to the material resources of the Empire. These have been allowed to rest either dormant or only partly developed. Few seemed to be interested in making

known their existence or in studying their possibilities. With the events of the war, however, a change has come about, and the world is brought to realize more and more how vast are the Empire's resources. Judging from the

latest official statistics there is room, for instance, for a large extension in British imports of timber from British North America. The following table reproduces the figures relating to such imports into the United Kingdom in 1914:

Official Statistics of Timber Imports Into United Kingdom During 1914.

Nature and Class of Material.	Canada.		Russia.		Sweden.	
	Loads	Value. £	Loads.	Value. £	Loads.	Value. £
Hewn: Fir, Pine and Spruce.....	10,276	96,456	172,436	308,510	39,755	102,979
Fir, sawn or split, planed or dressed....	785,289	2,579,992	1,707,992	5,005,000	1,045,038	3,089,395
Staves .....	244	1,791	38,693	237,848	21,514	68,345

IN A BRITISH COLUMBIA FOREST BEFORE LOGGING BEGINS.

The figures might be supplemented by those relating to railway sleepers, of which nearly 150,000 loads were imported from Russia and Sweden in 1914, compared with only 1,603 from British possessions. In furniture woods also, foreign countries supplied 138,000 tons as compared with only 87,000 tons from British possessions, Canada being represented by 12,600 tons. Furniture and cabinet ware was imported to the value of £304,000 from foreign countries, and to the value of only £5,000 from British possessions. Canada has also much leeway to make up in connection with house frames, fittings and joiners' work, which foreign countries supplied to the value of £144,800 compared with Canada's £8,300. The position is even worse as regards unenumerated wood ware and wood turnery, of which there was imported nearly £2,000,000 from foreign countries, and only £41,000 from British possessions.

### A Great Forest Region

The Pacific Slope is the greatest forest region in the world. Extending along the Continent, north and south for over 2,000 miles, and from the Pacific Ocean to the Rocky Mountains, it contains over half the standing timber of North America. Here are the forest giants of the earth, the oldest and the largest, yielding the clearest timber and in the largest dimensions. The Pacific forests are composed almost entirely of soft wood, i.e., coniferous or evergreen species—the wood which, most useful for general purposes, comprises over three quarters of the world's consumption. The most important varieties are Douglas fir, western hemlock, western red cedar, sitka spruce, western white pine, western larch, mountain western pine, redwood and sugar pine.

All these, except the last two, are found, and reach prime development in British Columbia in the northern central section of the 2,000 mile forest belt. The stand of merchantable timber in the Province is estimated to reach the enormous total of four hundred billion feet, board measurement, and the annual cut is at present only about one to one-half billion feet board measure. Thus it will seem that these forests can supply indefinitely the world's requirements for this kind of wood,

### Facilities for Shipments

Competition has necessitated the use of the latest machinery and methods. The extraordinary size of the timber, too, has compelled the adoption of the most powerful machinery and the best logging and saw milling; but, keen though competition is, enterprising firms, well seconded by the Provincial Government authorities, have been able to meet it, an important factor in their favor being the facilities present for

export. The practically inexhaustable supplies in size and quality have led to the production of all kinds of dimension timber, lumber, shingles, piling, poles, posts, railway ties or sleepers, pulp, paper and other wood products.

To assist in the shipment of these

there are numerous easily navigable inlets and channels indenting the coast and making the coast timber accessible. There are also many deep-water harbours suitable for mill sites, and for many other applications of water power, some of which are now in use. As these harbours never freeze, logging can be carried on all the year round. The mills whose capacity is much greater than their present output, have every appliance for shaping and finishing timber for final use. Dimension lumber is a specialty, and can be supplied in all sizes and of a quality obtainable from the Pacific Coast of North America alone.

### Leading Varieties—Douglas Fir

An interesting pamphlet dealing with "British Columbia Timber," issued by the British Columbia Government, gives intending purchasers much useful information with reference to the qualities and sizes of the principal export timber trees of the Province. Practically all the forest products at present exported by water are from the coast forests, the bulk being made up of four leading species—Douglas fir, western red cedar, western hemlock, and sitka or silver spruce. These are all giant timbers and are, perhaps, the most universally used woods obtainable in commercial quantities, one or another of them being suitable for practically every use to which wood can be put.

Douglas fir, also known as red fir, yellow fir, Oregon pine, Columbia pine or Douglas spruce, is recognized as the most important timber tree in the North American Continent. No other species exists in such great individual sizes, nor in such excellence of quality. It has been well described as the world's "All Utility" wood. The height of the tree is from 150 to 225 feet, with a diameter of 3 to 6 feet. Exceptional trees reach over 300 feet in height and 15 feet in diameter.

Though moderately hard, the wood is easy to work, straight grained, tough, resilient and durable. It varies in texture and color from fairly soft, fine grained, straw-yellow in narrow-ringed, slow growth trees, to a harder, coarse-grained reddish-brown in fast grown timber. When sawed tangentially the grain of the wood shows a beautiful figuring, rendering it very attractive for interior finish. It is the ideal building and structural timber, combining the requisites of great strength with light weight and ease in handling and working. Its high resistance to compression perpendicular to the grain, combined with its durability, has led to its adoption for railway cross ties or sleepers in Western America.

### Western Hemlock

Western hemlock, also called gray fir, Alaska spruce and Western hemlock fir,

DOUGLAS FIR TREE 500 YEARS OLD.

or spruce, is found in four species in North America. The trees are from 125 to 150 feet in height, and from 2 to 5 feet in diameter. The wood contains no pitch or resin, and is usually light in color, but often reddish-brown in the interior of the tree. Its strength, ease of working and freedom from warp distinguish it sharply from the hemlock grown in Asia. Western hemlock is at present manufactured into the common forms of lumber and used for the same purposes as Douglas fir.

It is particularly suitable for inside joists, scantling, flooring and ceiling

Asia which fell in damp woods centuries ago are found to-day still sound. Western red cedar trees range from 100 to 150 feet in height, with a diameter of 3 to 8 feet, although some are 15 feet in diameter. The wood is very durable and practically immune from decay. It is exceptionally light, soft, and of close, straight grain, making it easy to handle and to work, and rendering it remarkably free from warping, swelling or shrinking. Its slight aroma and freedom from pitch, make it especially suitable for moth-proof clothes chests, drawers, etc. It is the great source of

straight poles with their moderate taper, furnish saw timber of the best quality in large dimensions and unusually clear and free from defects. The color varies from white to white-tinged with a very little brown. It is soft and light, but tough and very strong for its weight. It is even-grained, long fibered, easily worked, non-resinous, odorless, tasteless, flexible and resonant. It does not warp or split, and therefore makes excellent core stock for veneered articles. Its strength, lightness, and lack of taste and odor make it particularly suitable for box and cooperage manufacture, especi-

IN THE FOREST.

IN THE FOREST.

work, and wherever ease of working, with a handsome finish and lightness combined with a large degree of strength, are required. Thus it is also valuable for the manufacture of boxes, barrels, sash and door stock, furniture, wainscoting and panelling. For paper-making, large quantities are now being used in the Western pulp mills. These mills and the saw mills of the Province cut 65,000,000 board feet of this timber in 1914.

#### Western Red Cedar

This is by far the largest of all cedars. It is a variety known from ancient times, and has been famous for its durability and resistance to decay. Cedar trees in

supply for shingle wood, and is also used for exterior siding, flume construction, canoes, row boats, trellis work, hot-house frames, sash frames, and wherever wood is required which must be exposed to the weather or moisture.

#### Silver Spruce

The Sitka or silver spruce, called also giant spruce, tideland or Alaska spruce, is another valuable forest tree of the Northern hemisphere, yielding excellent timber and being unsurpassed for pulp manufacture. Mature trees average 150 feet in height, and 4 feet in diameter, while some grow to over 200 feet high, and 10 to 15 feet diameter. The tall

ally where foodstuffs are packed. Sitka spruce is also well adapted for the manufacture of large doors, for garages, freight sheds and dock buildings. It can be used for framing, shelving, sheathing, and sub-flooring, where such qualities as ease of working and painting or light weight and ability to take and hold nails are demanded.

#### Official Information

The Forest Branch at Victoria, issues a pamphlet entitled "British Columbia Timber for Export," also for the builder and architect there are illustrated booklets entitled "How to Finish British Columbia Wood," and "British

Columbia Red Cedar Shingles," in the latter of which the illustrations show the attractive architectural style to which buildings thus roofed lend themselves. Copies of these, also that referred to on the previous page and entitled British Columbia Timber can be obtained from the Chief Forester, Forest Branch, Lands Department, Victoria, British Columbia, or from the Canadian Trade Commissioners, and the Agent General of British Columbia. The Forest Branch is not only thus laudably endeavoring to improve the trade relations between the provinces and other parts of the Empire and wherever timber is required, but is incessant in its endeavors to conserve and extend the forest wealth of British Columbia.

#### Promising Markets

In due time the ravages of the war will have to be made good, and it may safely be concluded that large quantities of British Columbia timber will be needed to rebuild the destroyed towns, villages, churches and mansions of

fir and two red cedar railway ties were recently forwarded by the Forest Branch of the Department of Lands to the Great Eastern Railway Co. The latter selected two sleepers from its stock which had been obtained from the Baltic, and tested the lot under similar conditions. The results showed beyond doubt the superiority of British Columbia Douglas fir for railroad ties. It was found that under compression Douglas fir stands 5,695 pound per sq. inch, as against 3,950 pounds for Baltic timber. Tension tests were even more favorable to Douglas fir.

#### IMMIGRATION TO CANADA ON INCREASE

IMMIGRATION to Canada is again on the increase, but the greater volume of it comes from the United States. For April and May, the first two months of the fiscal year, the total immigration was 12,791, as against 11,330 in the corresponding period, an increase of 13 per cent.

BEFORE THE ADVENT OF THE DONKEY ENGINE.

France, Belgium, Serbia and Poland. The general requirements will be for lumber suitable for buildings, common lumber for sheathing, studding, joists, rafters, cheap doors, sash, and timbers for the temporary reconstruction of railways, bridges, and other large works. Roofing will be in great demand. The competition will be between galvanized iron, prepared roofings and possibly shingles.

As regards railway ties or sleepers we may recall the fact that two Douglas

Of the aggregate 1,601 came from Great Britain, as against 2,697 a year ago, 10,279 from the United States compared with 7,877 in April and May of 1915, and 911 from other countries, compared with 756.

While the war largely stopped British and continental immigration, the influx from the United States to the western provinces has been steady, and promises to increase notably this year, owing to the demand for harvesters. Many of these come with the intention of permanently locating.

#### SHORT NOTICE CANCELLATION OF MUNITION ORDERS.

REPORTS from London that contracts recently placed in the United States for British shells have a cancellation clause effective any time after September 1, are characterized as ridiculous by men closely in touch with the placing of these contracts.

It is pointed out that deliveries in many cases will not have begun by September, nor, in fact, will the contracting concerns have had time to get in necessary machinery and supplies of metal. No company would make a contract involving a big outlay under such conditions.

The contracts for shells placed recently have not yet been signed, although the companies which received them are making the commitments for metals, etc. The majority, if not all, war contracts have a cancellation clause of some kind, but these all give the contractors a time allowance, usually three months. Besides, the purchasers contract, in case of exercising this clause, to make good not only all expenses undertaken in connection with the contracts, but all commitments made against them. No company would accept a contract without such a guarantee. In some cases a forfeit is added.

Granted that even a cancellation clause effective without notice were inserted in a contract, the company would still have considerable time to make deliveries, as the purchaser would have to pay for all material in process of manufacture, and the immediate stoppage of work on the contract would put on his hands a mass of stuff of little value except as junk, while the cost of permitting it to be completed would be small. The contracts closed recently are all for delivery up to March 31, 1917. That every company able to complete the contract within that time will have deliveries accepted may be regarded as certain.

A fruitful source of trouble in the matter of making deliveries of shells already contracted for has been the difficulty in obtaining fuses. Negotiations are now going on, and are likely to eventuate successfully, for the shipment of shells without fuses. It has been practically decided that not only Great Britain and France, but Russia, will also take American shells without fuses and obtain the latter elsewhere.

In regard to the difficulties that have been encountered, a banker well informed as to a number of contracts said there has been no trouble whatever with Great Britain or France, but that with Russia there has been "hell to pay." A complete change of the Russian attitude is now looked for.

# Synopsis of the Business Situation in Newfoundland

*The Empire call for men, naval and military, such as perhaps only Newfoundland can produce, and the hearty and generous response which it evoked, has, together with the shutting-out of much of its export trade for war reasons, contributed to place this old British Colony in a more or less precarious position commercially for the time being at least. Newfoundland, unlike Canada, has a very limited manufacturing community, her enterprise being directed almost wholly to the fisheries industry. Revenue required directly and indirectly for administrative purposes may therefore be said to entirely depend on the latter.*

**T**HE Budget speech of the Finance Minister of Newfoundland, presented at the close of the last session of the Legislature, indicated a situation which meantime was most gratifying, yet nevertheless containing a revelation of a serious financial situation which is likely to become more acute if the war is prolonged.

Newfoundland has faced some marked vicissitudes of fortune during the past quarter century—a fire which destroyed the greater part of St. John's in 1892; a bank failure in 1895 which gravely menaced her solvent existence and caused a financial depression for some years thereafter; fishery disputes with France, which were fortunately ended in 1904, but revived with the United States a year later, being ultimately adjusted before The Hague Tribunal in 1910. Political complications through all this period added to the problems of those entrusted with the colony government. Then two years ago the war broke out and added to Newfoundland's perplexities by first threatening the continuance of her fish trade with foreign countries and more recently by jeopardizing the future of her industrial advance through inability to obtain shipping for her needs.

## Meantime General Situation

Taking stock of the situation at the present time, the colony's position is as follows: Its public debt is about \$32,000,000, or, roughly, \$130 per head of the population. This, however, is not so serious by comparison with Canada, because there are no provincial, municipal, or other forms of subsidiary burdens such as have to be borne by the people there. For every public service is maintained in Newfoundland out of the general revenues, even the upkeep of schools, of the poor, the insane, and the sick, through asylums and hospitals. This burden is, however, increasing at the rate of, roundly, a million and a half dollars a year.

Newfoundland is maintaining on active service some 3,000 soldiers, in addition to 1,500 naval reservists, who are, however, financed by the British Admiralty as part of the Imperial naval organization. In addition, there is to be considered the question of pensions for incapacitated soldiers and for the dependents of those who die on active ser-

vice, while the colony is also pledged to supplement the provision made by the Admiralty for the naval men by amounts sufficient to bring their pensions up to the same figure as those provided for the soldiers.

Hence Newfoundland is facing serious financial burdens and is threatened with more serious ones in the future; and when it is remembered that the country has but one industry to depend upon—the fisheries, and that this is influenced largely by considerations in foreign countries where most of the fishery products go, it can be realized that circumstances may become such as to seriously threaten the maintenance of Newfoundland's individuality.

## Fat and Lean Years

Until comparatively recent years Newfoundland enjoyed periods of marked prosperity, due to high prices of fish, speculations in forest and mineral areas, and other industrial developments. These enabled her to accumulate substantial surplus revenues, with the result that in 1912 the latter amounted to \$500,000. This was kept as a nest egg for the proverbial rainy day, which, be it regretted, was not long in coming. In 1913 conditions were so favorable that it was resolved to risk a substantial reduction in duties on imports, equivalent to about \$400,000 a year, but the result was that in the ensuing budget a shortage of \$300,000 was faced because this reduction synchronized with depression in foreign markets and consequent reduction in imports from which the revenues of the colony are mainly derived. This compelled the Government to take \$300,000 from the cash reserve and apply it to liquidating this indebtedness.

Almost coincidentally with the opening of the fiscal year 1914-1915 on July 1 the war began. This proved crippling, because dealers imported as little as possible, not knowing how matters would develop, and the operations for that financial year, which ended on the 30th of June, 1915, showed a deficit of \$750,000 on a gross revenue from all sources of, ordinarily, four million dollars. This deficit was met by taking the remaining \$200,000 of the cash reserve and raising a loan of half a million dollars from the Bank of Montreal, carrying the remaining \$50,000 as a debit balance into the account of the current fiscal year. At

the same time, a special session of Parliament was held as soon as war broke out, extra duties were imposed, and for the current fiscal year, which ended on June 30 of the present year, a readjustment is assured, as everything points to the fact that enough revenue will be derived from the various sources of supply to meet all demands and yield a reasonable if not a generous surplus.

For the nine months ending March 31, the Customs revenue was about three million dollars, or within a few thousand dollars of the whole sum realized for the twelve months of the previous year, and huge imports are being made, so that altogether unexampled receipts are being recorded in the Customs department. Consequently, it is safe to conclude that at June 30 there would be enough cash in hand, not alone to meet all the year's obligations, but to leave something over as well.

## Need of Revenue

Now a new complication is introduced. At the session of 1915, the Legislature, in response to numerous and insistent demands, decided to go in for a policy of total prohibition of the liquor traffic if a vote of the electors decided therefor, and arrangements were made for a plebiscite in November last which, when it took place, resulted in the country declaring for prohibition. The Act creating the plebiscite provided that the liquor traffic should cease on Dec. 31, 1916, and the country is now within four months of a termination of this business. Simple, however, as this outcome might be from some view points, it also brought financial embarrassments in its trail, because the duties obtained from liquor imports amounted to, roughly, \$400,000 a year, and the effect of this will be felt almost immediately, as liquor dealers are now importing only enough for their requirements up to the end of the present year.

Beginning on January 1, 1917, the colony will have to devise ways and means whereby this shortage is to be met. No doubt it will be partly met by the increased purchases of duty-paying goods which will follow as a result of the betterment in the conditions of the families of the individuals who heretofore wasted their substance in dram drinking, but it would be absurd to suppose that this will, for some years at least, restore a

financial equilibrium. In some quarters it is suggested that it can be met by extra taxation, but already there are many protests that taxation in the country is as heavy as people can stand.

Some method of taxation will, however, have to be devised, but the Government decided that, in view of the unsettled conditions resulting from the war and the fact that there seems to be a prospect of sufficient revenue being obtained in the meantime to meet requirements to postpone the consideration of this problem until the next session. In the meantime they will make a full study of the liquor problem in regard to its bearing on the revenue and call an early session of the Legislature in 1917 if necessary in order to adopt measures to cope with the problem, so that as soon as the liquor business ends other machinery will be put into operation to make up the shortage which would otherwise result.

A further complication will be introduced by the fact that if the war continues, additional financial provision will have to be made to meet requirements in this respect, and since the rate of interest on loans for the colony has gone up from 3½ per cent., which it was before the war, to 5½ per cent., it follows that from the viewpoint of interest charges the actual burden is relatively increased by 50 per cent. In other words, a given amount appropriated for interest will now only secure a loan of two-thirds the amount it would before the war, and hence, as borrowings annually are much greater each year now than they were before the struggle the weight of the burden is increased disproportionately as well. It must follow as a consequence that unless methods of taxation can be devised which will yield an amount far exceeding anything procurable in the past, through the normal agencies of imposing duties on imports, there will be a hiatus to be met which will defy the ingenuity of the colonial authorities and which may compel a turning to some other sources to assist out of the embarrassments.

### War and Revenue

The situation is likely to be further complicated by the fact that owing to the war conditions, especially in Southern Europe, and the growing burdens upon the countries in that section of the world which take great quantities of Newfoundland codfish, prices are likely to fall, and thus the purchasing power will be reduced. The following series of figures for the past five years show the trend of exports, it being borne in mind that since 1911-12 the export of pulp and paper, a new industry, has represented two and a half million dollars annually:

1910-11 .....	\$11,975,747
1911-12 .....	13,874,809

1912-13 .....	14,572,889
1913-14 .....	15,134,543
1914-15 .....	13,136,880

A similar condition of things is shown by the totals of imports for the same period, from which it will be seen that in the first year of the war the colony's imports were reduced by virtually three million dollars as compared with the previous year:

1910-11 .....	\$13,383,910
1911-12 .....	14,733,499
1912-13 .....	16,012,365
1913-14 .....	15,193,726
1914-15 .....	12,350,786

The extent of the recovery of the past year has been such as to put it beyond all question that the decline last year was directly attributable to the war. For virtually every week of the fiscal year there has been a substantial increase in Customs revenue, totalling \$757,788 up to March 31. The barometer of Customs revenue for the past five years tells the story as follows:

1910-11 .....	\$2,898,615
1911-12 .....	3,184,633
1912-13 .....	3,282,304
1913-14 .....	3,089,627
1914-15 .....	2,744,567

### Customs Revenue

The actual Customs revenue for the nine months of this year was \$2,712,000, or almost exactly the same amount as was received for the twelve months of last year. This clearly proves that when the war broke out importers, instead of renewing their stocks, abandoned importing in large measure and tried to utilize the goods they had on their shelves. Thus imports contracted largely in volume, and Customs receipts were diminished, until now, having sold out these goods, dealers are having to import largely, and as they have to pay a much increased price for the commodities over last year, the revenue is gaining in two ways—first, by the duty on the increased quantity of imports; and second, by the additional amount obtained from the increased cost of goods themselves.

The war has, of course, increased the price of all commodities, and in a country like Newfoundland, which imports nearly everything that is used except a small quantity of foodstuffs, the effect of this condition has been to greatly increase the first cost of all articles.

### Imports

An analysis of imports under their four principal divisions, namely, from Britain, Canada, United States, and all other countries, shows the situation during the five-year period represented by the foregoing figures to have been that the decline was all embracing. Thus, whereas in 1910-11 the imports from Britain were about three million dollars, they increased in 1913 to nearly four and a half million dollars, and dropped

again in 1914-15 to two and a third million dollars, the decline that year being exactly a million and a half dollars, as against only \$600,000 the previous year.

With regard to Canada, the imports grew from \$4,600,000 in 1910-11 to \$5,200,000 in 1912-13, and declined again by \$700,000 last year. So also with regard to the United States. Imports from that country advanced from \$5,000,000 to \$5,800,000 and dropped again last year to \$5,000,000, while what was obtained from other countries advanced from \$740,000 in 1910-11 to \$820,000 in 1912, and declined again to \$590,000 last year. These figures, showing the same trend in all cases, make it evident that Newfoundland's most prosperous year was 1912-13, that the depression throughout the world the following year reduced imports by a million dollars in round figures, and that then, the following year, as a result of the war, a decline of three times that amount materialized.

### Exports

A similar analysis of exports to Britain, to Canada, to America, and to other countries discloses the following result: Exports to Britain increased in five years from \$2,300,000 to \$3,200,000, the figures remaining about constant for the last three years; the increase being due in great measure to shipments of pulp and paper. Exports to Canada increased from \$1,750,000 in 1910-11 to \$2,250,000 in 1912-13, dropped \$250,000 the next year, and dropped a further \$600,000 the past year, a fact ascribable to there having been exported comparatively no ore during the first year of the war. Exports to America increased from one and a quarter million dollars to nearly \$1,700,000 in 1913-14, while the decline last year was only \$150,000, showing that the articles sent to the United States are what may be described as absolute necessities, and, therefore, not easily reduced in either volume or value. Exports to other countries grew from six and three-quarter million dollars to somewhat over eight million dollars the year before last, and then dropped again to seven million dollars in the last fiscal year, the exports of lobsters and iron ore to Germany contributing in a large degree to that falling off.

Moreover, it must not be forgotten that for the fiscal year 1914-15 there was exported only 1,094,244 quintals of fish against 1,247,314 quintals the previous year, a reduction of 153,070, which at slightly over \$6 a quintal, represents a million dollars in itself, or one-half of the total decline in exports during the twelve months. The reduction in total trade, imports and exports, during the last fiscal year by over five million dollars or 20 per cent. of the whole effected itself in a decline in general revenue of \$365,689, or an average of one thousand dollars a day for the whole twelve months.

REVIEW OF OVERSEAS TROOPS BY DUKE OF CONNAUGHT. CANADIAN NATIONAL EXHIBITION.

## The Canadian National Exhibition, a Unique Enterprise

By C. T. R.

*This is the 38th consecutive year of the Canadian National Exhibition, it having come into existence as long ago as 1879. On the coming occasion, bigger enterprise and bigger financial outlay are planned by the Executive, and evidences available at the moment point to the realization of an all-round success that may easily surpass the most spectacular of any hitherto achievement. The 1916 Exhibition opens on August 26, and closes September 11.*

NO more fitting subject for feature in an export issue of Canadian Machinery could well be chosen than that of the Canadian National Exhibition held each year during the closing days of August and early September at Toronto, Ont. The reputation of the Exhibition is world-wide for the comprehensiveness of its display, and in its many-sided enterprise is reckoned to take first place among similar short-term undertakings on this or any other continent. Each year there is exempli-

NOEL MARSHALL,  
President, C.N.E., 1916.

tunity for business interests abroad to secure first hand and tangible data relative to the establishment of reciprocal trade relationships.

The Canadian National Exhibition is always worth a visit; in war times it is doubly so. There is all the realism of great battles that have thrilled civilization, a fascinating touch of the world war being everywhere apparent. A model camp contains a large detachment of overseas troops, living under active service conditions; there are reviews by State, Government and military officials; an exemplification of trench warfare; destruction of battleships on the water-

front by hidden mines; invasions by battleplanes and battles between the birdmen and land batteries of anti-aircraft guns; an immense munitions exhibit; bomb and hand grenade throwing; shells in process of manufacture; in short, Canada militant at a glance, real "preparedness" at its best.

The C. N. E. is world-famed for its superb pageants. This year all previous efforts will be eclipsed. The spectacle will symbolize and epitomize "Empire

GEORGE BOOTH,  
Only living original Director.

fied a fuller development of Canada's resources—mineral, agricultural and industrial, affording thereby an oppor-

JOSEPH OLIVER,  
Past President, C.N.E.

Federation," and will be of unusual magnificence, a gorgeous, satisfying, prophetic simile of Empire brotherhood.

It will include a majestic assemblage of troops from all sections of the British domains, and the reproduction on a mammoth scale of the British Houses of Parliament, Westminster Abbey, and a section of the War Office. This historic scenic setting from the "heart of London" lends itself to an unusual degree of brilliancy in costuming and general effects. A stage of 700 feet long is required; there will be a choir of 60 trained voices, 400 musicians, and 1,200 performers in all!

#### Some Leading Statistics

The accompanying general statistics reflect to some extent the importance of this National Institution, which in its every feature stands for Dominion-wide progress as well as for patriotic inspiration and preparedness:

Year.	Receipts.	Attendance.
1879 .....	\$ 57,296	101,794
1899 .....	109,085	....
1909 .....	249,603	752,000
1912 .....	384,708	962,000

1913 .....	459,238	1,009,000
1914 .....	336,150	762,000
1915 .....	356,502	864,000

Largest attendance on one day was Labor Day, 1913, 154,000 people; largest one day attendance, 1915, 141,000.

Annual distribution in prizes and special attractions, amounts to \$200,000.

sixteen thousand eight hundred people.

Permanent population of grounds during Exhibition, 10,000.

Average daily attendance, 1915, 72,000.

Average annual surplus paid to City of Toronto, 35,000.

Average paid in year 1915, 45,000.

ON-SHORE VIEW OF WATER FRONT, CANADIAN NATIONAL EXHIBITION.

#### Initiation Credit

The Exhibition was originally made possible by the liberality of the citizens of Toronto, and its later development to the unselfish efforts of public spirited men, leaders in agriculture, commerce, manufacturing, the professions and public life generally, who have unstintingly devoted themselves

Has been held annually for 38 years.

Area of Exhibition park, 264 acres.

Extent of waterfront, 1½ miles.

Value of buildings, \$2,500,000.

Floor space for exhibits, exclusive of live stock and outdoor area, square feet, 700,000.

Seating capacity of grand stand,

to the perfection of the undertaking, giving unsparingly of their time and best thought that the people might be instructed and amused, as well as being afforded an opportunity to realize the possibilities of their magnificent country and the extent of their national heritage in addition.

GOVERNMENT BUILDING, CANADIAN NATIONAL EXHIBITION, WHERE PROVINCIAL PRODUCTS ARE HOUSED.

After nearly forty years of cumulative effort everything that represents Canada's very best effort in all that goes to make a nation great is here centred and concentrated for the judgment of the people in such a way as to set up new standards of Canadian endeavor and stimulate energy and excite national ambitions. The whole resources of Canada are levied upon to make it a truly Canadian enterprise, yet, while essentially national, the Exhibition is at the same time international and even universal in scope and appeal.

The Exhibition is housed in and comprises a great natural park, 264 acres in extent, and constituting a veritable garden spot, with wide paved streets and walks, vistas of velvety green sward, enriched with a profusion of shrubs, trees and sub-tropical flowers blended into harmonious effects; stately permanent buildings, graceful and rich in architectural detail, valued in the aggre-

gate at \$2,500,000, and pleasure grounds valued at a similar sum, with their models of landscape artistry sloping picturesquely from the blue waters of Lake Ontario, along which they stretch for 1½ miles. This is the magnificent setting which adds so tremendously to the charm of the C. N. E., the greatest short time

community with a permanent population during Exhibition time of 10,000 people. It has its own post office, telegraph and express offices, police station, fire department, hospital, bank, and an electrical plant to care for 60,000 lamps. When not in use for Exhibition purposes the grounds become an ideal recreation spot for the people of Toronto, offering exceptional facilities for all sports and pastimes. There are 73 buildings on the grounds used for Exhibition purposes. The main group numbers 12, all being permanent structures of steel, brick or concrete construction. Particulars of the leading buildings follow:

OFF-SHORE VIEW OF WATER FRONT, CANADIAN NATIONAL EXHIBITION.

exhibition in the world. In this pleasant environment the people of Canada pause each autumn to take a national inventory, to see how they have progressed as a nation within an Empire, and prospered as a people during the year.

Exhibition City is a self-contained

Manufactures No. 1 Building.—This magnificent palace of industrial arts and crafts has an imposing appearance and contains 72,500 square feet of exhibit space. It is ideally located in the centre of the grounds, facing upon the beautiful Grand Plaza. It is well lighted, and

THE GOODERHAM FOUNTAIN AT NIGHT, CANADIAN NATIONAL EXHIBITION. MANUFACTURERS' BUILDING IN BACKGROUND.

is designed to be an almost perfect exhibition structure. Here are displayed annually outstanding triumphs of human

space in these two structures alone of 145,000 square feet for the exposition of our mechanical and commercial effort.

tains much that is typical of the enterprise and progress of the Dominion and Provincial Governments, epitomizing in

BIRDS-EYE VIEW, CANADIAN NATIONAL EXHIBITION

ingenuity and skill, an imposing array of Canadian scientific and industrial achievement and endeavor. Manufactures No. 2 Building has approximately the same exhibit space, making a total

**Government Building**—This really graceful structure with its massive towers and commanding dome combines both utility and beauty. It is located near the main entrance to the park, and con-

ains much that is typical of the enterprise and progress of the Dominion and Provincial Governments, epitomizing in an attractive and instructive way the possibilities of the country, developed and otherwise. It contains 48,400 square feet of exhibit space.

**Horticultural Building**—This is per-

GOVERNMENT BUILDING AT NIGHT, CANADIAN NATIONAL EXHIBITION.

haps the most attractive building architecturally on the grounds. its majestic dome towering to a great height, while its stately entrance lends it great dignity and beauty. It has a floor space of 30,000 square feet, and is utilized for the exhibit of fresh fruits, vegetables, palms, flowers and kindred branches of husbandry.

**Transportation Building**—For exhibition purposes this structure compares equally with those already mentioned. It is 337 feet long by 153 feet wide, and contains 50,000 feet of unobstructed floor space, every inch of which is laid out to the best advantage. Spacious aisles and exceptional facilities are, therefore, provided for demonstrating the selling points of automobiles, supplies, etc., which fill the structure to overflowing during the two weeks of the Exhibition each autumn.

G. H. GOODERHAM, M.P.P.,  
Chairman Sports Committee.

**Industrial Building**—This contains 76,500 square feet, and is devoted largely to the exposition of the heavier lines of manufacture, such as electrical equipment, stoves, etc. One wing is devoted exclusively to appliances and processes of manufacture, the latter contributing infinitely to the interest and educational value of the Exhibition as a whole.

**Dairy Building**—A floor area of 25,000 square feet gives ample room here for demonstrations on a broad and comprehensive scale of all that is modern and pertinent to the equipment and management of dairies and cream factories. Butter and cheese making are exemplified in a practical and instructive manner.

**Fine Arts Gallery**—This handsome structure has housed many of the world's famous art treasures. A great variety of exhibits from home and abroad is each year to be found in the Fine Arts Gallery, and thus a wide con-

DR. J. O. ORR,  
General Manager, C.N.E.

stituency of visitors is appealed to. The building contains 7,000 square feet. Applied Arts have a beautiful building on the Plaza devoted exclusively to that feature.

**Machinery Hall**—This contains the products—still and operating—of many of the great metal-working shops of Canada, and serves to reflect the wonderful development taking place in steam, electrical, hydraulic and mechanical engineering. The building has 35,000 square feet. Plans have been

JOHN G. KENT,  
Past President, C.N.E.

prepared for a much larger and more modern structure, and one more commensurate with our achievement.

In addition to the above, there are the Railways Building, with 18,500 square feet; Administration Building; Poultry Building, 30,000 square feet; Dog Building, pretentious stables for the accommodation of hundreds of horses under one roof, and over two score other buildings devoted to general live stock purposes.

**Grand Stand**—This is thoroughly fire-proof, being of steel, reinforced concrete and pressed brick construction. It is over 700 feet long and seats 16,800 people. Thousands more can be accommodated on the lawn enclosure. In connection, there is a magnificent  $\frac{1}{4}$ -mile track and a mammoth outdoor stage.

### The Agricultural Side

Everything possible is done by the Canadian National Exhibition to exploit the science of farming and advanced

COL. W. K. McNAUGHT, C.M.G.,  
Chairman Reception Committee.

animal husbandry, and to solve the problems of agricultural betterment. After the strenuous days of harvest is over, the Exhibition, therefore, proves an irresistible magnet for the farmer and the breeder. In the live stock department are found the most perfect specimens from the country's herd builders, and a C. N. E. prize-winner is the last word in Canadian cattle breeding.

Liberal increases in cash prizes, more extensive accommodation as the years pass and convenience of time and place have made the display famous the world over. Handsome, costly stables for horses, cattle, sheep and swine, a beautiful poultry building, where thousands of the pick of the feathered kingdom are gathered annually are to be found erected and equipped. Elsewhere grains and other agricultural products are shown in profusion, marvellous evidence that Canada is the land of plenty and the C. N. E. her show window. A visit to

the Canadian National Exhibition is equivalent to a short cut in Canadian agricultural education.

Abundant proofs that Canada is holding her own in industrial pursuits are on every hand. The very latest that mechanical skill and inventive genius have devised are here displayed in a manner worthy of their importance, and not a few manufacturers from other parts of the world seize the opportunity to bring their wares prominently before the Canadian people.

#### Educational Side

While much attention is devoted to the material phase of things, an equal spirit of enterprise and perfection of detail is noted on the educational and inspirational side. Proceeding on the theory that culture is most essential to counteract the materialistic tendencies of the age, art and musical programmes are arranged upon a scale of exceptional magnificence. Amidst the dazzling attractions and beauties of park environment will be found spacious band stands, where famed musical organizations give a score of concerts daily, while two beautiful buildings—the Fine Arts and Applied Arts—house famous works of several continents. This year the paintings will include over 200 masterpieces of French art, a contemporaneous exhibit representing the general trend of French art at the present time. The masters of all schools, from the old-established academic branch to the revolutionary leaders of the new modernist schools, are represented. Another building is devoted to other cultural and educational exhibits, including the work of the High, Public

and Technical School pupils and University students. The agricultural colleges and the governments also contribute educational exhibits and give demonstrations relative thereto.

#### Amusement and Entertainment

In addition to the educational features, the amusement and entertainment

include a majestic assemblage of troops representing all sections of the British Empire domain. There will also be reproductions on a large scale of the British Houses of Parliament, Westminster Abbey and a section of the British War Office. This historic setting from the very heart of London lends itself to an unusual degree of brilliancy in costum-

ing and general effects. Some 1,200 performers, 400 musicians and a choir of 60 trained voices will take part in the display

#### Exhibition Date and Duration

The Exhibition is open two weeks each year—the last week in August and the first week of September, the total annual attendance approximating 1,000,000 people, equal to about one-eighth the entire population of Canada. People come from all over the continent each year, and railway men describe this annual Canadian festival as the greatest creator of traffic in North America. It attracts at a conservative estimate 400,000 visitors to Toronto annually, and what this means to business in actual dollars and cents is beyond computation. There is no line of business that does not feel the vivifying influences of such a great influx of temporary population, and the value of it as a trade factor is perhaps best described in the words of a prominent member of the Board of Trade, who declares that the City of Toronto could “profitably conduct the Exhibition on an annual deficit of \$100,000.” As a matter of fact, the Exhibition, instead of a deficit, pays over to the city a nice little nest egg each year, which helps keep down the tax rate.

A treasure house of enjoyment and

SEMI-TROPICAL SCENES, CANADIAN NATIONAL EXHIBITION GARDENS.

ends are well looked after, each year furnishing a programme of attractions rich in wonder and variety, including a mammoth spectacle in front of the Grand Stand. This year the pageant will symbolize and epitomize “Empire Federation,” and will be of unusual magnificence, a satisfying simile of Empire brotherhood and cohesion. It will

education, the colossal dimensions of the institution amaze the visitor here for the first time, while the magnitude of its undertakings and the inspiration and great impetus it imparts to Canadian industry generally make it the pride and boast of the whole Canadian people. It long since broke through local limitations, and is in every sense a national, even an Empire, asset.

Perhaps one of the best remembered indications of the enterprise and boldness of the C. N. E. were the exposition some years ago of the late Queen Victoria's Jubilee presents, valued at £1,000,000 sterling, and the gathering of Cadets from all over the Empire for an Imperial Review, Australia, New Zealand, Ireland, England, and Scotland contributing a number of contingents of boy soldiers to the event. For some years one of the leading British military bands was brought across to lead the musical programme, these including the bands of the various regi-

ments of Guards. Plans were under way to extend the list, but unfortunately the war intervened.

#### Housing Foreign Exhibits

Before the European war cloud burst, negotiations were about completed for the erection of national buildings by

Canadian National for the exposition of the products in which they excel.

Such a proposition has often been talked of, and recent events may hasten it, thus fulfilling the prediction of Earl Grey, former Governor-General of Canada, who was a firm believer in the future of the C. N. E.

In his address in 1911, the seventh Exhibition during his stay in Canada, his Excellency said: "Seven years ago its buildings were flimsy and unpretentious. There were no exhibits from outside Ontario. Now you have two millions invested in permanent buildings. These fine structures and the permanent staff connected with them have enabled your To-

ronto Exhibition to throw off the modest and provincial robes in which she was gowned when I first had the honor of making her acquaintance, and to garb herself in all the dignity and majesty of National and Imperial robes. I should like to congratulate Dr. Orr, the man-

CROWD SCENE AT REAR OF GRAND STAND, CANADIAN NATIONAL EXHIBITION.

France, Japan and a couple of the present enemy countries. The expectation now is that as a result of the war and the prospective closing of trade relations within the Empire that others of the Overseas Dominions will see the importance of having representation at the

ENTRANCE TO HORTICULTURAL BUILDING, CANADIAN NATIONAL EXHIBITION. TRANSPORTATION BUILDING ON LEFT.

ager, and the directors. It is my firm impression that they have builded better than they knew. I believe the Exhibition is destined to become not only a more and more important national exhibition of the Dominion of Canada, but also in time a world-embracing Exhibition of the whole British Empire. You are peculiarly well situated for such an Exhibition. The wise and generous liberality of the City of Toronto, and the readiness with which your public-spirited citizens have placed their valuable and disinterested services at your disposal, have made it possible for you to contemplate developments, which, in proportion as they are realized, will have

thus demonstrating its utility in war as well as in times of peace.

#### This Year's Munitions' Exhibit

One of the big educational attractions this year will be the exhibit of munitions. The whole process of shell manufacture will be shown from the rough forging to the finished projectile, and added interest will be lent to the display by the presence of various explosives and chemicals that enter into the manufacture of munitions. In all, thousands of shells with their constituent parts, including instructional sectional views, will be shown. One of the most interesting features will be contri-

Base plates, 18-pdr. H.E., Welland Vale Mfg. Co., St. Catharines.

Base plates, 4.5 howitzer, Whitman & Barnes, St. Catharines; Montreal Ammunition Co., Montreal; Canadian Locomotive Co., Kingston.

an influence of far-reaching effect on the life of the Canadian nation and on its place in the Empire of the Crown."

#### Winter Military Camp for Overseas Units

In 1914, when it grew too cold for the soldiers in training at the summer camps, the Government took over the Exhibition for military purposes, and thousands of men and horses were housed there. Last winter between 8,000 and 10,000 men were again accommodated. It proved an ideal mobilization camp, and no better trained men have been sent out of Canada than those who received all or part of their training at the Exhibition camp, the C. N. E.

buted by the Dominion Arsenal at Quebec, which will send the model exhibit from which Col. Lafferty and his staff gave instructions to engineers from various Canadian firms just about to enter the shell trade. There will be two process exhibits showing the actual manufacture of shells, also a series of moving pictures taken in the factories with the permission of the Government and the Imperial Munitions Board. Among the firms which will contribute to the exhibit are the following:

Adapters No. 4, Toronto Plate Glass Co., Toronto.

Adapters, 8 in., Canadian Ingersoll Rand Co., Sherbrooke, Que.

Bullets, Brandram-Henderson Co., Montreal.

Boxes, 4-round, Malcolm Suter Furniture Co., Hamilton.

25-round brass cartridge shipping cases, Lalley Lacrosse Mfg. Co., Cornwall.

Boxes, 2-round, 60-pdrs., Benson & Bray, Midland; Gold Medal Furniture Co., Toronto; Office Specialty Co., Newmarket.

Copper bands, 18-pdr., Metal Drawing Co., St. Catharines; Canadian Westinghouse Co., Hamilton.

Copper bands, 4.5, Rome Mfg. Co., Rome, N.Y.; Dominion Copper Products Co., Montreal.

Canadian Car & Foundry Co., Montreal.

P. W. Ellis & Co., Toronto.

Dominion Arsenal, Quebec.

the C. P. R., which for some time past has had efficiency experts at work throughout the Dominion reporting on the practicability of using waste materials to manufacture various lines previously imported.

### QUEBEC BRIDGE.

THE superstructure on the Levis side of the Quebec bridge will, it is expected, be completed very shortly, and the contractors hope that the central span, 640 feet in length and weighing 6,000 tons, will be placed in position some day between the tenth and fifteenth of September, the exact date and hour de-

The Ross Rifle Co., Quebec.

Consolidated Mining & Smelting Co. of Canada.

### Canadian Toy Exhibit

Approximately 30,000 toys made in Canada by the forty firms now engaged in the work will be shown at the Exhibition, one whole wing of the Government building being devoted to the display. Watson Griffin, of the Department of Trade and Commerce, has returned to Ottawa after several days spent in Toronto arranging for the exhibit, which will be taken over and handled by the Government. An exhibit of German and Austrian toys, which the Canadian product is displacing, will also be on view for the purposes of comparison.

A unique section will be furnished by

pending on the wind and tide factors.

In order to complete the plans for floating the immense central span into position, a close study had to be made of the tide in the vicinity of the bridge, and experts have done this in a very careful manner. The approaches and the cantilever were practically completed last year, while that of the Levis side is practically so, leaving the placing of the central span as the remaining unit yet to be accomplished. The large traveler used on the north side of the bridge was taken down last spring and re-erected just below Pointe aux Pizeau at Silvery, where it is to be used to place the central span on barges, the latter to be floated to the bridge side at the proper height of the tide.

### THE 1916 CANADIAN NATIONAL EXHIBITION

THE forthcoming Canadian National Exhibition gives promise of recognizing to a greater extent than has any of its predecessors the place and part that our metal-working industries fill in our national progress, and in turn reflect on our international status. As will be noted from the general article covering the initiation, development and past accomplishment of the C.N.E., and from the programme of this year's now imminent annual display, there has been arranged to feature, in manner becoming our manufacturing enterprise and achievement, the production of shells and shell parts from their minutest detail right up to the stage of complete assembly for service in the field.

In arranging to recognize in this special manner what our metal-working plant executives and operators have, during these twenty months or more, accomplished on behalf of our Empire, the Exhibition management are to be congratulated. It goes to show that, although the machinery side of the Exhibition scheme of things has in the past been somewhat secondary in importance, if steps be taken—and the time never was more opportune, to erect a Machinery Hall commensurate with the scope of the metal-working industries and with the reputation of the Exhibition as an educative and nation-building enterprise, the myriad industries concerned—large and small, will be found ready and willing to annually tax such a building to its fullest capacity with worthy examples of craftsmanship.

The European War has opened up to us new fields of commercial endeavor, but back of commerce we must have industry, and the latter must needs have inspiration to keep it progressive. The Canadian National Exhibition as an annual institution may well provide the inspiration for our industries. Few of our manufacturers would now be disposed to rest on their oars to the extent of allowing exhibits of one year to remain publicly and be in a market sense outclassed by a competitor in the succeeding year. Whatever of that nature has prevailed in the past, the new vision of accomplishment and the new appreciation of capacity that have come to us, make repetition absolutely impossible.

Incidentally, we might say, that munitions manufacture in Canada, and the coming display at the C.N.E. constitute an inspiration to the Exhibition executive, and one which is perhaps more forcefully expressive of the need

for a new Machinery Hall than the much urged action towards same to which they have become so well accustomed, particularly around Exhibition time in recent years.

### OUR FAVORABLE TRADE BALANCE

THE piling up of bank deposits in Canada continues unabated, and, as a phase of national strength, may be said to augur well for our bearing somewhat comfortably the war-imposed burdens already effective and those yet to be enacted. It must be admitted, however, that our financial strength arises largely from the widespread production of munitions by our manufacturing plants to order of Great Britain and her Allies. Further, our reasonably satisfactory trade balance has its foundation and superstructure centred also about munitions. There is nothing, of course, undesirable about such a state of affairs, provided its maintenance had even some degree of permanency, for then, even with heavy imports against us, we might still easily keep "afloat," so to speak.

Fortunately, in the most desirable sense of the term, this munitions business is only temporary; but are we acting as if it were so. We have talked of new opportunities for export trade and the capturing of former German trade which is both domestic and export, yet seem to have accomplished little in either direction. Our imports are increasing by leaps and bounds, aside from raw material requirements for munitions, and just where we will ultimately land unless we call a halt and proceed to manufacture, instead of continuing to buy "ready for service," the "gods" alone can supply the answer.

The export opportunities for Canadian plants with organizations, equipment and product to take advantage of them are numerous, and not a few of our industrial enterprises are already and profitably thus engaged. The question naturally arises are our myriad other firms, unadapted for export business, doing their part in keeping imports at the absolute minimum. It appears to be fully established that they are not, particularly as far as Western Canada is concerned. From apparently reliable sources the manufacturers of Eastern Canada are not even recognized as competitors in the market for Western business.

Export opportunities, as already stated, were never so attractive and inviting. Offsetting imports by meeting their variety production with the new capacity that munitions manufacture has engendered is equally attractive and inviting, while at the same time never more necessary of becoming operative.

### HONOR TO WHOM HONOR IS DUE

IN the Meredith-Duff Commission Report regarding the distribution of fuse contracts, etc., special mention was made of the part played by Col. Cantley in the initiation of shell manufacture in Canada. The work of that gentleman has, however, been largely obscured through the precipitation of our munitions activities into one more or less political melting pot. Some notice has, of course, been taken, in that Col. Cantley has been made an Honorary Colonel in the Canadian Militia.

To what extent, we ask, does such a distinction meet the situation. Col. Cantley is in the forefront of the "Builders of Canada," not as a soldier although equally effective, but as the "Man Behind the Gun," and in the broader sense, as an Empire defender and builder. Of the three most active and prominent members of the Shell Committee, Sir Alexander Bertram, Col. David Carnegie, and Col. Cantley, the two former have received more or less substantial Government recognition, although in their case little has been bestowed or given to brag about, when a full inventory is made of their achievement. That due to Col. Cantley still tarries.

## INDUSTRIAL NOTABILITIES

**J**OHNN CUNNINGHAM McLENNAN, B.A., Ph.D., F.A.A.S., F.R.S.C., F.R.S., Professor of Physics and Director of the Physical Laboratory, University of Toronto, was born at Ingersoll, Ont., April 14, 1867, the son of David and Barbara (Cunningham) McLennan. He was educated at the Clinton and Stratford Collegiate Institutes, the University of Toronto, and the University of Cambridge.

On completion of his university courses, Mr. McLennan became assistant demonstrator of physics at the University of Toronto, in 1892; demonstrator of physics in 1899; associate professor of physics in 1902; director, the Physical Laboratory in 1904; and professor of physics in 1907, which latter two appointments he still holds.

JOHN CUNNINGHAM McLENNAN.

Mr. McLennan is President, the Alumni Association of the University of Toronto; President, the Royal Canadian Institute, 1916; a bureau of scientific and industrial research, and a school of specific research having recently been added to the other spheres of that body. He is a Past President of Section III., Royal Society of Canada; Past Vice-President, B.A.A.S., and became a Fellow of the Royal Society of London, in 1915. Numerous papers on "Radio Activity," "Electrical Conduction in Gases," and "Spectroscopy," etc., have come from his pen.

Mr. McLennan married Elsi Monro Ramsay, daughter of William Ramsay, Bowland, Scotland, on September 15, 1910. His clubs are the York, Toronto Golf, and Faculty Union (University of Toronto), and his recreations golf and tennis.

In politics he is an Independent, in form of religion a Presbyterian. His residence is 88 Prince Arthur Avenue, Toronto, Ont.

demand. The galvanized situation has been somewhat disturbed by the recent decline in the price of spelter, but the situation at present is showing improvement. Wire interests are comparatively quiet, but are preparing for an expected increase in fall business. No change is noted in quotations, but a re-adjustment of prices, especially in galvanized products, is anticipated. All other lines of steel and iron products remain unchanged, and may remain so, awaiting further developments.

**Metals**

The general tone of the metal situation shows little change. Prices have been fluctuating under uncertain conditions. Copper has become steadier, owing to the lack of second-hand metal, which has been affecting the market for some time. Tin is unsteady after a period of good inquiry. Spelter is again showing signs of a relapse, and domestic demand is weak. Lead is quiet and easier. Antimony remains very quiet under easier prices. Aluminum is a little stronger.

**Copper.**—During the past week the copper situation has shown improvement, owing largely to the gradual disappearance of re-sale metal. For the past few weeks the market has been gauged by the activity displayed in second-hand copper, and as it is apparently difficult to find sellers of second-hands at present, the situation is becoming steadier and prices firmer. The firm tone is additionally emphasized by the fact that futures are commanding full prices. The demand is not heavy, but inquiries are of sufficient volume to indicate the trend of the market. The strength of the London market is reflected in the quotations for the week, which show an advance of £14 on Standard spot and also on futures, the present price being £105 and £103 respectively. Electro copper, while not very active, is firm at £123, an advance on the week of £1. In response to the higher prices in foreign markets, and the evident shortage of prompt metal, New York reports an advance of 1c. on electrolytic and 1½c on castings. Lake is firm at 25½, and current quotations on electro and castings are nominal at 26c and 24½c per pound. Dealers here report a little more activity, but quotations are unchanged at 31c for lake and electrolytic, and 30c for castings.

**Tin.**—No developments have transpired during the week and the situation is practically unchanged. The only feature of interest is the better inquiry from small consumers, as the larger users of metal continue to manifest an attitude of indifference. From present conditions it would appear as though consumers were using up some of their safety stock, giving little thought to future conditions, or living in the expectation of an early settlement of hostilities opening the way to an easier situation. However, while

## The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

**Montreal, July 29, 1916.**—Weather conditions are having a detrimental effect on the industrial situation. With the temperature at the high level of the past few weeks, and the impossibility of maintaining the high pressure of business, production has been greatly curtailed. However, activity throughout all lines of industry is still great. Munition plants are all fully engaged and little abatement is noticed. Considerable activity is being shown in the paper making industry; many plants enlarging their facilities to meet the rapidly increasing business.

**Steel**

All branches of the steel industry are comparatively quiet, but the market continues strong. The production has been

somewhat curtailed, owing to the hot weather, and the output for July will likely be lighter than that of the previous month. The feeling appears general that the steel situation is very firm, and will remain so for some time. The demand for open-hearth billets and sheet bars is exceptionally heavy and Pittsburgh prices have been advanced \$3 per ton. The situation in plates is becoming more acute, as the demands for shipbuilding are constantly increasing, and the mills are already booked far in advance. Possibilities of an increase in price seem more than likely. The requirements of the trade for electrical sheets are very heavy, also for all gauges of blue annealed sheets. Black and galvanized sheets are in fair

tin may be in a safer position in this respect than some of the other metals, there is little to indicate that future conditions are free from some of the obstacles that have arisen in the past. In the absence of demand both here and abroad the market is inclined to weaken. London quotations have declined £2 10s. on Standard spot and Straits, and £2 5s. on Standard futures. Latest prices quoted are £165 15s. for Standard spot, is £168 10s., which is a decline of £1 10s. during the week. The New York market has fluctuated for the past week of 38c, being a decline of ½c on last week's quotation. The local situation shows little activity on a weak market. Prices are easier at 43c, a decline of 1c per pound.

**Spelter.**—The recent strength, which has developed after a comparatively long period of weakness, appears to have stopped, leaving a tone of uncertainty. A factor that bears on the present situation is that of wages and operating expenses. These have increased to such an extent that very little profit is to be derived by selling spelter under 9 or 10c. The activity shown by galvanizers, when spelter was selling around 9c. has fallen off and the domestic demand at present is very light. The London market, while showing an advance of £5 on spot and £3 on futures, is at present developing a weaker tendency; latest quotations are £59 for spot and £53 for futures. New York quotations seem to indicate that the recent strength may be of short duration, as a decline of ¾c is noted in the latest report. Nominal quotations are 10.3c per pound. The local situation is quiet, but dealers intimate that a weakness may develop shortly; prices are nominal at 15c per pound, 1c lower than last week.

**Lead.**—The market is quiet and unchanged. Buying is light, but it is thought that consumers want lead, and an active movement would develop, if quotations were easier. Unless the volume of business increases, declines are expected. London cables show a closer margin between prompt and time delivery. Spot prices having declined and futures advanced slightly. The trust price is firm at 6½c, and outside interests are quoting 6¼c, a decline of over ½c per pound. Local conditions are unchanged, but a weakness is apparent, and dealers have reduced their price to 8½c per pound, a decline of ½c.

**Antimony.**—No new developments have arisen to change the stagnant condition of the market and dealers are unable to define the situation. New York reports another decline of ½c, the quotation of 13c being no key to the exact position, as sales of metal have been made at lower figures. Dealers here report a weak and quiet market, with quotations at 19c, a decline of 1c on the week.

**Aluminum.**—The market is slightly

stronger owing to the scarcity at present and dealers are able to command better prices. Dealers here have advanced their quotations to 68c, an advance of 3c per pound.

#### Machine Tools and Supplies

The machine tool situation continues to reflect the activity throughout the metal working industry, but the volume of business is assuming more normal proportions. Recently placed orders for the larger shells have resulted in additional business, but in the majority of cases orders have gone to plants already equipped. Owing to many plants having finished their work on the lighter shells, the market is beginning to carry various lots of second-hand machinery. The delivery on new and standard equipment is much better. The situation as regards supplies is unchanged.

#### Scrap

Slight improvement is reported in the old material market, but few price changes are reported. Chicago prices on

#### CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion \$100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

heavy steel scrap have advanced, price quoted being now 15¼c. Price at Pittsburgh is 16¼c, which is ¼c less than the previous week. The strength in copper is improving the scrap situation a little. Local dealers report slightly better conditions, with prices generally firm.

**Toronto, Ont., Aug. 1.**—The general industrial situation continues very satisfactory. Factories working on war orders have as much business as they can conveniently take care of especially in view of the scarcity of skilled labor and, in many cases, shortage of raw materials. Munition plants have sufficient business on hand to keep them operating at capacity for many months and further contracts have been assured by the action of the Dominion Government in establishing additional credits on behalf of the British Government. These contracts will represent heavy tonnages of steel and result in considerable activity in the trade. The steel trade is exceedingly prosperous, due to the shell orders and also because of the large export business in shell steel, billets, wire rods, wire nails, barbed wire, etc. Machine tool

builders are also enjoying the greatest prosperity ever known in the history of the trade. One of the most interesting features has been the development of special tools for the production of shells and shell parts, while the general efficiency in machine shop practice has been considerably improved notwithstanding the scarcity of skilled labor.

A statement recently issued by the Department of Trade and Commerce reveals the big advance which has been made in Canadian trade during the first three months of the present fiscal year, April to June inclusive. The statement shows an increase of more than 93 per cent. in the grand total for the above mentioned three months. The volume of trade aggregated \$527,512,344 as against \$272,646,868 for the first quarter of the fiscal year of 1915. June was an exceptionally good month, the exports showing very heavy increases in manufactures, in agricultural and in mineral products. The figures in the report are very significant and prove conclusively that the country is enjoying an era of prosperity never before experienced.

#### Steel.

Domestic business is quieter and there are no developments of particular importance to note. Export demand continues heavy but the warm weather is generally affecting the steel trade. Prices of steel products are unchanged, but holding firm. Deliveries on boiler tubes continue backward, as makers are sold out for six to eight months. The wrought iron pipe situation is unchanged and prices of galvanized pipe have not been lowered yet, although there is a possibility of some action being taken in the near future. The situation in plates is steadily getting tighter and there is a possibility of higher prices due to increased demand from shipbuilding interests.

The market for black and blue annealed sheets is strong and prevailing quotations are being firmly held. An advance in black sheets is likely in the near future owing to the higher prices of sheet bars which are now in effect. The market for galvanized sheets is irregular owing to the spelter situation. The decline in quotations of galvanized sheets in the States has been followed by some makers advancing prices, while others have not done so. Quotations locally are steady at the decline announced last week.

Orders for large shells have been placed in the States by the Allies and negotiations for further orders, representing heavy steel tonnages are under way which is tending to stiffen the market. Export demand continues heavy for Bessemer and open-hearth billets and sheet bars, shell steel, wire products, structural steel, etc. The big demand for

billets has caused an advance in prices and a scarcity of semi-finished steel. Bessemer billets have advanced \$2. and are now quoted at \$42 per ton. Open-hearth billets and sheet bars have advanced \$3 and are now quoted at \$45 per ton. Pittsburgh steel bars are unchanged at 2.50c, plates 3.50c, and shapes 2.50c Pittsburgh. The ferromanganese situation is unchanged, prompt and forward metal continuing to be available in carload lots around \$175. per ton, seaboard.

#### Pig Iron.

The market continues quieter and domestic demand comparatively light. The consumption of steel making grades continues heavy which is emphasized by the fact that the Steel Company of Canada will have shipped to Sarnia, Ont., during the present season of navigation 500,000 tons of iron ore from the ranges near Superior and Duluth.

#### Scrap.

The market for most old materials is quiet and there is little of interest to note, as the situation generally is practically the same as during the past week or two. Although prices are unchanged, there is a weaker tendency in some materials, notably zinc and lead.

#### Machine Tools.

Interest is still centered almost entirely on munitions contracts, and a good demand for tools for machining large shells is anticipated for some time to come. Large contracts for shells have recently been closed in the States by the Allies for delivery April 1917, which is an indication that further big orders will be placed in Canada for large calibre shells. The last order received by the Imperial Munitions Board amounts to \$35,000,000, and covers shells ranging from 6 in. to 9.2 ins. calibre.

#### Supplies.

Business continues active for practically all machine shop supplies, including small tools, drills, chucks, taps and dies, belting, etc., while the demand for waste has been so heavy that manufacturers have been unable to supply all that was required. Some lines, particularly those composed of steel or brass are difficult to obtain promptly, and prices are still high. Prices generally are firm and steady with no change of importance to note.

#### Metals.

An improved tone has developed in the metal markets, and with the exception of lead and antimony there have been no further declines. The improvement in the situation is due to increased demand, and the markets generally, with the above exceptions, are more active. The copper market is stronger as a re-

sult of increased enquiry and the gradual absorption of resale metal. Tin is also in better demand and the market is more active. The downward movement in spelter has been checked and, although quotations are unchanged, the market has a better tone. The lead market continues weak and prices are lower. Antimony has also declined but aluminum is a little higher. Solders are unchanged.

**Copper.**—The market is firmer and more active but quotations are unchanged and entirely nominal. Resale copper is being gradually absorbed and there are indications of an improvement in demand which is tending to stiffen the market. On the other hand, producers who have been holding their prices are taking more interest in the market and are more inclined to sell. Local quotations are firm and unchanged at 29c per pound.

**Tin.**—The market is firm and unchanged with a better tone. The New York market is firm at advanced prices and supplies are coming forward in satisfactory volume both from England and from the Far East direct. Local quotations are unchanged at 44c per pound.

**Lead.**—The market is dull and easy with local quotations lower. The Trust are holding their prices at 6.50c New York, but the independent producers are quoting 6.25c. It is generally believed that present prices will not hold unless there is a considerable improvement in business, as it is well understood in the trade that production is exceeding consumption. Lead has declined ½c locally and is quoted at 8½c per pound.

**Antimony.**—The market continues extremely dull and the demand is light. Quotations are lower and nominal at 19c per pound.

**Aluminium.**—The market is a little more active and quotations are higher at 68c per pound.

cannot be confirmed at present. Cyanamid is a patented fertilizer product for the manufacture of which the chief raw material is lime stone. There are also valuable by-products, which can be utilized in the production of calcium carbide and ammonia.

A primary essential is an abundance of cheap water power, and as regards the raw materials and the power the Reid interests are the fortunate owners of almost unlimited supplies capable of development in the same locality.

The limestone deposit towers over the Humber River, which flows into the Bay of Islands, on the south-west coast of the island colony, and the same river is capable of producing all the power necessary for an extensive plant such as is proposed. While coal, the third principal ingredient necessary, is not so close at hand, it can be cheaply handled from the mines in Cape Breton by water, only a few hours' sail away.

It is claimed that the "cheap assembling of all the necessary elements will enable the company to manufacture cheaper than any other country in the world engaged in that business, Norway now having the credit of effecting the cheapest production. All the products it is aimed to turn out are standard commodities, and have a world-wide market.

#### LAKE STEAMSHIP DEAL IS RATIFIED.

THE purchase of St. Lawrence & Chicago Steam Navigation Co., by Canada Steamship Lines, already approved by the directors, has been formally ratified at a meeting of shareholders of the latter company.

It was explained by J. R. Norcross, vice-president, who presided in the absence of the president, Mr. James Caruthers, that the opportunity of purchasing the controlling interest in the company presented itself some time ago, but, because Canada Steamships was unable to secure complete control, the governors of the guarantee fund refused to sanction the purchase.

Later on a syndicate, made up of directors of the Canada Steamships Company, purchased the stock, and now proposed to turn over to the company 9,664 shares of the St. Lawrence & Chicago Steam Navigation Company at a price of \$187.75 per share. In addition to this, which was the purchase price of the shares, the syndicate will receive an amount equal to the net earnings of the St. Lawrence Company during the period from April 20 to July 31, the period during which the property was in their hands.

The transaction, it was pointed out, would not involve new financing, nor yet constitute a charge on earnings. The

#### NEWFOUNDLAND INDUSTRIAL CORPORATION PROMOTION.

SIR W. D. REID, president of the Reid Newfoundland Railway and allied companies, who returned to St. John's a few days ago, is understood to have spent considerable time in New York in the past year promoting the financing of a big corporation for Newfoundland, which, if successful, would mean a tremendous industrial impetus for Ancient Colony.

Two or three months ago the prospectus was completed of a proposed \$15,000,000 Cyanamid Corporation, and hopes are entertained that the necessary capital will be procured from American sources to proceed with the erection of the plant. Some days ago reports were current in St. John's that the necessary capital was assured, but this

funds required were already in hand in the fund made up of money received as insurance for vessels lost and further the company being acquired had some \$400,000 cash in its treasury.

### CHANGE IN SHELL STEEL

A HALT in the manufacture of shells in Canada for the Allies has, we understand temporarily been called, as a result of changes in the specifications of the steel required, which have just been made by the Imperial authorities.

The change is the requirement of steel of a higher tensile strength than had hitherto been specified. It will, of course, be quite possible to manufacture this steel in Canada as hitherto, but as large orders for steel of the quality formerly suitable have been given, and there is a large stock of manufactured shells on hand, some inconvenience may be caused.

Large orders for shells of 9.2 and other large calibres have recently been placed in the United States, and it is

understood that others will be distributed in Canada.

The first samples of time fuses produced at the loading plant established in Montreal by the Munitions Board have successfully passed the tests. No shipments have yet been made, however, it is understood, and it is not altogether likely that the board's expectations as to early delivery, expressed during the fuse contracts inquiry, will be realized.

Hand grenades, the weapons which are proving so valuable and effective in the present war, are now being manufactured in Canada. They are being loaded, however, in Great Britain.

### CANADIAN HOLIDAY RESORTS

**The Lake of Bays**, situated in the famed "Highlands of Ontario," has scenery rugged enough to be romantic and yet beautiful to the eye. The altitude is 1,000 feet above the sea, the air rare and invigorating, and skies usually clear and beautifully blue. It is easy of access by the luxurious trains of the Grand Trunk Railway system. Reasonable charges and first-class accommodation is to be had at

the different hotels; just the place for a summer outing. Handsomely illustrated descriptive literature on request.

**The Algonquin Provincial Park of Ontario** is a region of expansive lakes abounding with the gamest of fish, of hurrying streams, primeval forests of pine, spruce and fir, where almost every species of fauna roams in freedom; cool winds; ideal camping spots and sylvan retreats—everything, in fact, that is dear to the heart of the lover of outdoor life. It is situated 2,000 feet above sea level, 205 miles west of Montreal, 170 miles west of Ottawa, and 200 miles north of Toronto. This unspoiled tract of 1,754,473 acres is one of the most attractive playgrounds of Canada, having unlimited attractive canoe routes, splendid fishing, purest of air and great opportunities for the kodak operator. For those who desire city comforts in the wilderness there are hotels and log cabin camps. Illustrated descriptive matter sent free on application to any Grand Trunk agent, or Miss Jean Lindsay, manager, Highland Inn, Algonquin Park Station, Ontario.

## CANADIAN COMMERCIAL INTELLIGENCE SERVICE

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

# INDUSTRIAL <sup>A</sup><sub>N</sub><sup>D</sup> CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

## Engineering

**St. John, N.B.**—A power house will be built at the General Hospital here by the City Council.

**Winnipeg, Man.**—The Manitoba Power, Pulp & Paper Co., of this city, propose erecting a saw and paper mill at Grand Rapids.

**Montreal, Que.**—Announcement has been made that the G. T. R. will build extensive car shops at Port Huron, Mich., to cost \$750,000.

**St. Boniface, Man.**—D. Blachensky proposes to build an abattoir and packing plant here, to cost \$75,000. Plans have been prepared.

**Tecumseh, Ont.**—The Eau Claire Waterworks Co. has secured a site, 50 x 125 ft., and will shortly call for tenders for the erection of a plant to cost \$20,000.

**Stratford, Ont.**—The Stratford Brass Co., manufacturers of brass fixtures, is building an addition to its plant, 42 x 42 ft., two storeys. Alfred Hahn is manager.

**Montrose, Ont.**—The Canadian Aloxite Co., a subsidiary of the Carborundum Co., Niagara Falls, N.Y., is erecting a plant on an 8-acre site near here. The main furnace building will be built 60 x 220 feet; the other buildings will be

used for receiving and mixing ore and accommodating the crushing machines.

**Winnipeg, Man.**—D. B. McDonnell, of this city, is interested in a \$150,000 hydro-electric project on the Saskatchewan River, at Grand Rapids, to operate a paper mill.

**Cobalt, Ont.**—The Dixon Creek (Cobalt) Silver Mining Co. has ordered a new 5-drill Ingersoll-Rand compressor plant and the machinery is expected to be on the ground early next month. H. Hollands-Hurst is mine manager.

**Haileybury, Ont.**—The School of Mines on which work has been started by the contractors Secord & Sons, of Brantford, Ont., will contain assay and balance rooms, mill room, forge, carpenter, and machine shops, stamp mill and crushing room. The school will be equipped with modern appliances and will be in charge of A. E. Flynn.

**Renfrew, Ont.**—Owing to the serious shortage of power here, it is proposed to develop 1,500 h.p. at the first chute of the Bonnechere River, or to enter into an agreement with M. J. O'Brien, of Renfrew, to take power from his proposed plant on the Madawaska River at Calabogie. Mr. O'Brien has offered to supply 3,000 h.p. almost immediately.

**Port Arthur, Ont.**—At the Western Dry Dock & Shipbuilding Company's plant, progress is being made with the two new shops being built to replace

the pattern and electrical shops destroyed recently by fire. The brickwork on the electrical shop is nearly completed and the building is almost ready for roofing. The pattern shop is not so far advanced, but the concrete is being poured in for the foundations and piers, and this will be rushed to completion.

## General Industrial

**Toronto, Ont.**—Bowles Lunch Co. will build a bakery at a cost of \$30,000.

**Hamilton, Ont.**—The Appleford Counter Check Book Co. propose building an extension to their factory.

**London, Ont.**—The Canadian Cereal Mills Co., propose building an extension to their mill here to cost \$10,000.

**Regina, Sask.**—The Prairie Biscuit Co. will build a factory here to cost about \$25,000.

**Ottawa, Ont.**—Grant Holden & Graham, lumberman's supplies, will build a factory at Ottawa, to cost \$30,000. James Mather, of Ottawa, is the architect.

**Waterloo, Ont.**—Considerable loss was sustained by Messrs. Wallace & Robinson through a fire which occurred at their plant on July 26. The damage has not yet been estimated, but it will amount to several thousand dollars, and is only partially covered by insurance.

## Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

### BRAZIL

Bahia, British Consul.  
Rio de Janeiro, British Consul General.

### CHILE

Valparaiso, British Consul General.

### COLOMBIA

Bagota, British Consul General.

### ECUADOR

Quito, British Consul General.

### EGYPT

Alexandria, British Consul General.

### FRANCE

Havre, British Consul General.  
Marseilles, British Consul General.

### INDIA

Calcutta, Director General of Commercial Intelligence.

### ITALY

Genoa, British Consul General.  
Milan, British Consul.

### MEXICO

Mexico, British Consul General.

### NETHERLANDS

Amsterdam, British Consul.

### PANAMA

Colon, British Consul.  
Panama, British Vice-Consul.

### PERU

Lima, British Vice-Consul.

### PORTUGAL

Lisbon, British Consul.

### RUSSIA

Moscow, British Consul General.  
Petrograd, British Consul.  
Vladivostok, British Consul.  
Odessa, British Consul General.

### SPAIN

Barcelona, British Consul General.  
Madrid, British Consul.

### SWEDEN

Stockholm, British Consul.

### SWITZERLAND

Geneva, British Consul.

### URUGUAY

Monte Video, British Vice-Consul.

### VENEZUELA

Caracas, British Vice-Consul.

## For Rough Turning 8", 9.2" and 12" Shells

A study of this machine will show you what can be accomplished when a scientific knowledge of the requirements of heavy duty lathes is applied in practical form. This machine has withstood for years the acid tests of criticism and its record of deeds accomplished will inspire confidence in this big 16,000-lb. giant.

It is a powerful machine arranged for rough-turning 8", 9.2" and 12" shells. Power is transmitted through an 8" driving belt with three instantane-

ous speed changes through hardened steel gearing. 6 1/2" face on main driving gear. Four instantaneous feed changes all through cut steel gearing running in oil.

The A. R. Williams Machinery Co., Ltd.

64-66 Front Street West, Toronto, Ont.

## Taper Threading With a Geometric Die Head is a Simple Matter

The chasers follow the taper of the work automatically, and release the work at the end of the cut. Head is withdrawn without touching the finished threads.

Geometric Taper Threading Die Heads are adapted to Screw Machines and Turret Lathes. When not cutting taper threads, the Head can be removed, leaving the machine free for other work.

Made to order, specially suited to requirements of machine and work.

Employed very generally at present on fuse work.

—Consult us about your taper threads—

A Geometric Taper Threading Die Head.

**The Geometric Tool Company, New Haven, Conn., U.S.A.**

Canadian Agents:

Williams & Wilson Ltd., Montreal.

The A. R. Williams Machinery Co., Ltd., Toronto, Winnipeg and St. John, N.B.

*If any advertisement interests you, tear it out now and place with letters to be answered.*

**Winnipeg, Man.**—The Western Canada Marble & Tile Co. has purchased a site at a cost of \$100,000, and will build a finishing plant, 52 x 175 ft. W. B. Purtell is president.

## Electrical

**Pembroke, Ont.**—The Pembroke Electric Light Co., will begin work in the near future on the erection of a sub-station.

**Guelph, Ont.**—The Light & Heat Commission will instal a 750-horse-power transformer in the Huskisson Street plant here.

**Dundas, Ont.**—An explosion followed by a fire did considerable damage to the Hydro generating station here on July 30.

## Municipal

**Hamilton, Ont.**—The city council propose building an extension to the Beach pumping station.

**Lyall, Man.**—It is proposed to instal an electric light and power plant at a cost of \$8,000.

**Vancouver, B.C.**—The City Council will call new tenders for 6 in., 8 in. and 12 in. steel pipe.

**Ridgetown, Ont.**—The Town Council will spend \$10,000 for additions to its waterworks plant and system. D. Cochran is clerk.

**Winnipeg, Man.**—A new motor will be purchased for driving the 5,000,000-gallon pump at the McPhillips Street pumping station. W. P. Brereton is city engineer.

**Chatham, Ont.**—The Chatham Electric Light plant was destroyed by fire on July 22, all the machinery being badly damaged. The loss is estimated at \$50,000 with \$11,000 insurance.

**Petrolea, Ont.**—At a special meeting the town council adopted a report recommending the taking over of the natural gas distributing plant by the town as a public utility.

**Toronto, Ont.**—Fire Chief Smith has reported to the Board of Control in favor of purchasing six pieces of apparatus for the department from the La France Co. at an approximate cost of \$50,000. The Canadian Seagrave Co. of Walkerville, also tendered. No award has been made yet.

**Windsor, Ont.**—City Engineer Edward Brian, of Windsor, has been chosen chairman of the Board of Engineers, which will prepare plans for a joint water and sewage system for Windsor.

Walkerville, Ford City, Sandwich, Ojibway and Sandwich West. Leonard Rice, assistant engineer of Ojibway, was elected secretary. Complete plans, with the cost, will be placed before Essex Border Utilities Commission in time for the ratepayers of each municipality to pass on the project at the January elections. Lake St. Clair may be the source of the new water supply, it is said, while a trunk sewer will be laid along the river front to a point near Amherstburg, where sewage will be treated before being sent to the river.

## New Incorporations

**The Snyder Desk & Table Co.** has been incorporated at Ottawa, with a capital of \$75,000, to manufacture furniture at Waterloo, Ont. Incorporators: H. M. Snyder, A. H. Snyder, and C. H. Snyder, all of Waterloo, Ont.

**H. Kutschke & Son** has been incorporated at Toronto, with a capital of \$40,000, to manufacture wood products at Pembroke, Ont. Incorporators are: H. A. Kutschke, G. C. F. Kutschke and C. F. Kutschke, all of Pembroke, Ont.

**The Chicago Construction Co.** has been incorporated at Ottawa, with a capital of \$40,000, to carry on the business of general contractors, with head office at Windsor, Ont. Incorporators: Morris Harris, F. T. Ranney and David Oppenheim, all of Detroit, Mich.

**The Quebec Shipbuilding & Repair Co.** has been incorporated at Ottawa, with a capital of \$40,000, to build and repair ships of every description. Incorporators: W. R. L. Shanks, F. G. Bush and G. R. Drennan, all of Montreal, where the head office will be located.

**The Dominion Steel Products Co.** has been incorporated at Ottawa, with a capital of \$500,000, to manufacture all kinds of machinery, tools, munitions, guns, etc., at Brantford, Ont. The incorporators are: W. S. Brewster, G. D. Heyd and R. T. McGraw, all of Brantford, Ont.

## Tenders

**Matheson, Ont.**—Tenders will be received until August 8 for the construction of a waterworks system. Particulars may be obtained from McAuslan & Anderson, North Bay, Ont.

**Drummondville, Que.**—Tenders will be received August 15 for the construction of mechanical gravity filters, with a capacity of 500,000 U.S. gallons per day, also supplementary tenders for plant without machinery. Consulting

engineers, M. M. Ouimet & Lesage, Montreal.

**Seagrave, Ont.**—Tenders will be received until August 8 for the construction of a 50-ft. bridge across the Non-quon River, near here. Full particulars may be obtained from the engineers, Bowman & Connor, 31 Queen street West, Toronto, or the county clerks at Lindsay and Whitby, Ont.

**Lethbridge, Alta.**—Tenders will be received up to August 5 for the complete installation of a filtration system, capacity three million Imperial gallons per twenty-four hours. Plan showing location of buildings and elevations can be had by making application to the Public Works Department. A. M. Grace, Commissioner of Public Works.

**Winnipeg, Man.**—Tenders will be received until August 21 for the various works required in the completion of the New Parliament Buildings, and not included in the general contract. The works include structural steel, heating and ventilation, electrical conduit and wiring. Particulars may be obtained from S. C. Oxtun, Deputy Minister of Public Works, Winnipeg.

**Ottawa, Ont.**—Tenders addressed to J. W. Pugsley, secretary, Department of Railways and Canals, Ottawa, Ont., will be received up to August 7 for the construction and erection of passenger station at Halifax, N.S. Plans, specifications and blank form of contract may be seen at the offices of the following: Chief Engineer, Department of Railways and Canals, Ottawa, Ont.; Chief Engineer, Canadian Government Railways, Moncton, N.B. Superintending Engineer, Halifax Ocean Terminals, Halifax, N.S.; Ross & Macdonald, architects, Montreal and Toronto. Contractors who wish to obtain plans and specifications temporarily for their own use, may obtain same from Ross & Macdonald, Montreal, on depositing with them a certified bank cheque for \$100, which will be refunded on the return of the plans and specifications to them.

**Assiniboia, Sask.**—Tenders will be received up to August 8, for the supply and delivery of the following machinery and materials: (A)—For the supply, delivery and erection of an 150 h.p. internal combustion engine; (B)—For the supply and delivery and erection of generator, exciter, switch board, and other apparatus; (C)—For the supply, delivery and erection of pumps, motors, piping and air compressor; (D)—For the supply and delivery of two pneumatic storage tanks; (E)—For the supply and delivery of one oil storage tank; (F)—For the supply and delivery of poles, wire and line material; (G)—For the supply and delivery of approximately 17,500 feet of 4 in., 6 in. and 8 in.

steel pipe, or cast-iron pipe, and specials; (H)—For the supply and delivery of 20 hydrants, 29 gate valves and boxes; (J)—For the erection of power station; (K)—For the supply, delivery and installation of heating plant. Complete sets of plants and specifications may be seen at the office of the consulting engineers, Murphy & Underwood, Saskatoon, Assiniboia, Sask.

## Personal

Thos. Geoffrey Leith, manager of the Canadian head office of the British Aluminum Co., has joined the Imperial Air Service.

E. R. Wood, of Toronto, was elected president of the Buffalo, Lockport and Rochester Railway Co., at a special meeting of the Board of Directors of that concern, recently held in Syracuse, N.Y.

Sir W. D. Reid is at the head of the proposed \$15,000,000 Cyanamid Corporation which is being organized to establish a plant for making a patent fertilizer.

Frank W. Baillie, president of the Canadian Cartridge Co., Hamilton, Ont., has returned to the Government \$750,000, the firm's profits on war orders to date. The money returned is to be used for patriotic purposes.

John H. Allen, president of the John F. Allen Co., New York, makers of the original "Allen" riveting machines, died recently at Kattskill Bay, N.Y. The deceased, who was in his 58th year, had been president of the company for the last 15 years, succeeding his father, who founded the business 45 years ago.

John Conway, for over forty years lock-master at No. 2 Lock of the Lachine Canal and a well-known figure in the port of Montreal, died recently, in his 80th year. For the greater part of his long life he was to be found at his post at No. 2 Lock and as a result he was known to, and a friend of, all the crews of the boats passing through the canal.

## Trade Gossip

**Brockville, Ont.**—The Canadian Briscoe Motor Co., are establishing a plant here for making drop forgings and other automobile parts.

**Two Russian Ports.**—In 1915, more than half of Russia's exports, and nearly half of her imports, passed through the port of Archangel, on the White Sea. Imports at Vladivostok rose from 19 million rubles in 1913 to 301 millions in 1915.

**Hawkrige Brothers  
Company**

303 Congress St., BOSTON, MASS.  
U.S.A.

**Sarnia.**—The Mueller Mfg. Co., Sarnia, Ont., has received a contract from a big munition firm in the States to supply them with brass forgings for time fuses.

**Ottawa, Ont.**—The International Nickel Co. has authorized the incorporation of a Canadian subsidiary company, designed to construct and operate a plant for refining nickel in Canada.

**Montreal, Que.**—Shareholders of the Canada Steamship Lines, at a special meeting held here on July 27, approved the regulation recently passed by the Board of Directors authorizing the purchase of the St. Lawrence & Chicago Steam Navigation Co.

**Marine Insurance Revenue.**—Twenty-three British Insurance companies in 1915 received \$63,500,000 in marine insurance premiums, and paid claims amounting to \$36,300,000, the loss ratio thus being about 57 per cent., against a ratio the previous year of 61½ per cent.

**Great Copper Find.**—It is reported that a sensational find of copper running \$100 to the ton, has been made northwest of The Pas in the Beaver Lake district. The Hayden-Stone company of New York, has taken an option on it at \$3,500,000. Ten million tons have been blocked out by diamond drill tests. A great mining industry is expected in that region.

**Ottawa, Ont.**—It is reported here that the International Nickel Refining Co., of New Jersey has practically abandoned the idea of establishing its Canadian refining plant on the Atlantic seaboard or elsewhere in the Maritime Provinces, after making a thorough canvass of the eastern situation, and that the plant will be erected almost immediately, probably somewhere in Ontario, close to the fields of ore production.

**Welland, Ont.**—Welland was recently visited by four representatives of the International Nickel Co., who are seeking a location for a Canadian plant to refine nickel ore. The visitors were Frank Ludlan, general purchasing agent; W. L. Wotherspoon, consulting engineer, R. C. Stanley, general superintendent, and C. Bradigan, chief engineer. They require fifty acres of land and 500 electrical horse-power. Hamilton was also visited.

**Canadian Ore Shipments.**—The Steel Co. of Canada, Hamilton, Ont., will have shipped to Sarnia, One., during the season of navigation upwards of 500,000 tons of iron ore from the ranges near Superior and Duluth. This is the greatest tonnage ever ordered to be shipped via Sarnia and will consist of nearly a hundred ship loads. The ore

will be loaded in cars at Point Edward had hauled to Hamilton.

**Trade Committee Successful.**—Word has been received in Ottawa that the commission of Canadian business men which, accompanied by Sir George Foster, has been touring Great Britain and France investigating trade conditions, has met with every success. It will not be through, however, with its work before the end of August.

**Brantford, Ont.**—Officials of the Dominion Steel Products' Co. met officials of the Manufacturers Committee of the City Council last Friday with a view to locating a large plant here. The company, for which a charter has been secured, with capital of \$500,000, has been incorporated for the primary purpose of manufacturing munitions. After the war another line of industry is projected.

**Ross Rifle Changes.**—The Ross Rifle Co. is negotiating with the Government for an amended contract looking to the manufacture of the Enfield rifle now that the Ross type of arm has been abandoned as the Canadian service rifle. Sir Charles Ross and Wallace Nesbitt, K.C., counsel for the company, have been in Ottawa in connection with the matter. The plant at Quebec will have to undergo extensive reinstallation to adapt it to making the new rifle, but this can be done. An arrangement has yet to be concluded finally, but the company plans to go ahead and manufacture the arm which replaces the one abandoned by the British authorities as unsuitable to service conditions. What to do with the thousands of Ross rifles which have been discarded is still an open question.

### Nickel Refining Company Formed.

The Canadian branch of the International Nickel Co., which is to undertake the manufacture of nickel in Canada, has been incorporated at Ottawa by letters patented under the name of the International Nickel Co., of Canada. The new company is empowered to produce, refine, smelt, etc., nickel, copper, iron, steel, cobalt and other minerals, and to occupy and develop lands and concessions relating to or containing nickel, copper, iron, etc. The incorporators of the new company are Britton Osler, K. C., Toronto; W. A. J. Case, and the usual number of office employees. A meeting of representatives of the Ontario Government will be held in Ottawa very shortly, when the plans of the company and the question of the selection of a site will be taken up. The new plant will probably be built in units, and will provide a production of 12,000,000 to 15,000,000 pounds a year at the beginning.

## "PERFECTION"

THE NAME

THE DESCRIPTION

Sizes 16x6, 18x8, 20x10

**Edgar Bloxham, Inc.**

Grand Central Terminal Building

NEW YORK, N.Y., U.S.A.

Prices lower than any other lathe of same specifications because of volume of manufacture and fixed low percentage of profit over actual cost of production.

# SAVE YOUR MONEY

FOR THE

## DOMINION WAR LOAN

TO BE ISSUED IN SEPTEMBER.

By purchasing a bond you will help to **WIN THE WAR** and obtain for yourself an investment of the highest class yielding a most attractive rate of interest.

DEPARTMENT OF FINANCE  
OTTAWA.

Steel Shell Forgings or Billets of any size or weight will move any distance or about curves upon our specially constructed Gravity Carriers and Incline or Horizontal power devices. No labor required.

**Canadian Mathews Gravity Carrier Co., Toronto**

## KEYSEATER

for Milling Internal  
Keyseats

This tool is an attachment for the drilling machine, and is regularly made with straight shank for gripping in the drill chuck; taper shank can be had if desired. The tool is fitted with a high-speed steel rotary cutter for milling internal keyseats in one cut. To complete a keyseat it is only required to pass the tool through the hole just once. Innumerable inexpensive eccentric bushings are supplied whereby the tool may be bushed to meet any diameter above its own.

Write for Catalog C for full detail.

## FOR SALE

**HORIZONTAL GAS ENGINE 25 H.P. IN SERVICE** at present time, \$375.00 cash. Write Penberthy Injector Co., Limited, Windsor, Ontario. (5)

**FOR SALE OR RENT — MACHINE SHOP** with railroad siding. Box 208, Canadian Machinery. (4)

**A SNAP IN TURRET LATHES SLIGHTLY** used on shell work. Fourteen splendid machines at bargain prices. Do you need these machines? If so, drop a line to Box 953, Woodstock, Ont.

**LATHE FOR SALE—ONE 39 x 17-FOOT** Pond engine lathe, suitable for heavy shells; in good condition; \$1,500.00. A. B. Ormsby Company, Limited, Toronto. (2)

**A BARGAIN FOR QUICK SALE—30 H.P. 10 x 14 engine;** guaranteed in first-class working condition; drive belt included. Hamilton Whip Co., Hamilton.

**FOR SALE—SCREW-CUTTING LATHE, 14 FT.** bed, 16-inch Imperial chuck, 24-inch Swing Countershaft. Apply Thos. H. Ruth, 314 Pearl Ave., Peterboro. (1)

**FOR SALE—ONE DAVIS 4½" CUTTING-OFF** machine; practically new; been used less than three months; very reasonable. Canadian Linderman Co., Ltd., Woodstock, Ont. (tf)

**12-INCH HEAVY DUTY (CANADIAN CORPORATION)** moulder; just used six months; also band saw, shaper, buzz planer, used two years. Apply W. A. Rumney, 36 Fuller Ave., Toronto. (28)

**20,000 LBS. ½ GALVANIZED STEEL GUY** wire. We can offer this wire at very attractive prices. Winnipeg Machinery Exchange, Sutherland and Gladstone Sts., Winnipeg, Man. (25)

**1-2 SPINDLE SHAPER, WOOD TOP, JOHN Ballantyne, Preston, make.** used two months. 1 Dynamo, 45 lights. Toronto and Hamilton Electric Co. make. Used five months. Good as new. Box 195, Jordon, Ont. (R.T.F.)

**DROP PRESS FOR SALE—NO. 9 MINER & Peck drop press;** anvil 2,000 lbs.; base 30,000 lbs.; 36" between uprights; 40" x 35" between poppets; 34" x 29" top of anvil; guaranteed as good as new. Can be shown in operation to any genuine prospective buyer. The Metallic Roofing Co., Limited, Toronto. (4)

**FOR SALE — THREE HOLDEN-MORGAN** threading millers; one arranged for nose threading; two for base threading. One base threader can be changed to 4.5, as it was reduced from this size. Also two Bertram wavers and groovers, and one Martin, all used for 3.3 shells. Canadian Linderman Co., Ltd., Woodstock, Ont. (27)

**FOR SALE—5 CARLOADS MACHINERY** steel, consisting of rounds from ¼" to 5", squares, flats, angles and channels. Also tire sections. Slightly rusted through being outside. Will move this entire stock at great sacrifice in price to someone who can take delivery of entire quantity at once. This is an exceptional offer. Box 210, Canadian Machinery. (1)

## FOR SALE

**Fox Monitor Lathe, 18" x 5' 6",** 9-hole turret, cross feed, hollow spindle, 5-step cone; good as new. Plating dynamo, 6 volts, 250 amp.; used only a short time.

**PENDRITH MACHINERY COMPANY**  
970 Queen St. West, Toronto

**FOR SALE—NEW HAVEN, 60-INCH SWING** Standard Engine Lathe—triple geared. 15 ft. bed, hollow spindle, cuts threads 1 to 12. Compound rest, countershaft, steady rest, wrenches, etc. This tool is in excellent shape and owner offers special bargain. Particulars from Winnipeg Machinery Exchange, Sutherland and Gladstone Streets, Winnipeg, Man. (24)

**FOR SALE — AT ALEXANDRIA, ONT. —** Machine shop in two buildings; 10,500 sq. feet concrete floor space; equipped with lathes, shaper, planer, miller and variety of other iron-working machines and tools; good foundry in connection. Inventory of buildings, machinery and stock, \$64,272. Practically new plant, in good condition. F. T. Costello, Assignee, Schell F. & M. Co., Ltd., Alexandria, Ont.

**FOR SALE—McDOUGALL ENGINE LATHE** 20" swing, 10' bed, complete with 20" 4-jaw chuck, countershaft, steady rest, face plate, gears, etc. This tool, we understand, has never been used; has been lying crated for about 5 years. We are having it cleaned and offer a decided bargain for quick sale. Winnipeg Machinery Exchange, Sutherland and Gladstone Sts., Winnipeg. (3)

## SITUATIONS WANTED

**MECHANICAL AND ELECTRICAL ENGINEER,** 16 years' experience, plant layout and maintenance; expert draftsman; wishes change. Box 207, Canadian Machinery. (26)

**POSITION WANTED AS SALESMAN,** agent, or traveler, for mechanical goods, or machinery, by Chief Engineer, (Marine), thoroughly reliable, of good education and appearance. Box 209, Canadian Machinery. (3)

**MECHANICAL ENGINEER OPEN FOR POSITION** of shop superintendent. Wide experience in mining machinery and electric motors, hot water boilers and radiation. Experienced in tool-making, designer, and a keen cost observer. Has had seven years' foundry experience, familiar with moulding machines and a post-graduate of McLain's system of mixing iron. Familiar with shell work. Can give the best of references. Box 211 Canadian Machinery (4)

## REPAIRING

**ALL KINDS OF MACHINERY REPAIRED,** rebuilt and installed. W. H. Sumbling Machinery Co., 643 Yonge Street, Toronto, Ont.

## WANTED

**WANTED—ELECTRIC TRAVELLING GANTRY** crane, span about 57 ft., clearance 50 ft., overhanging at one end; load 15 tons. State full particulars and price. Thor Iron Works, Limited, Toronto, Ont. (27)

## WANTED

Burned out Tungsten Lamps, late type, drawn wire, 25, 40, 60 and 100 Watts, 110 and 115 volts.

**DOMINION TUNGSTEN LAMP FACTORY**  
ST. CATHARINES, ONTARIO

## FOR SALE

Two 24-inch standard Gisholt Turret Lathes, completely tooled for boring 4.5" H.E. Shells.

**Box 212**  
**Canadian Machinery**

# Some Scientific Aspects of Steel Founding Practice\*

By W. A. Naish, A.R.S.M., A.I.M.M.

*The following resumé of facts concerning steel is not put forward as representing new information, but rather with the idea of its being somewhat of an educational message to foundrymen and metal-working operatives whose sphere of activity does not permit of their becoming familiar with the essentials of steel production in specially equipped plants.*

**U**NDER the name "Steel" are now included so many varieties of iron that it is impossible to give a good definition of the term. Until the introduction of mild steel, the term steel was always defined as being iron containing from 0.5 per cent. to 1.5 per cent. carbon, with small quantities of other impurities, and which, when heated and quenched in water, became sensibly harder. Now, however, we have steels containing much less than 0.5 per cent. of carbon, and which do not sensibly harden on quenching. A definition now perhaps more accurate is "any form of iron other than malleable iron, containing 2 per cent. of carbon or less, with small amounts of other impurities."

## Classification.

There are many classifications, the most general, perhaps, being "hard steel" and "mild steel," the dividing line being taken at about 0.5 per cent. carbon. The two forms pass gradually into one another, and the hardening on quenching becomes less as the percentage of carbon decreases. Another classification is "high," "medium" and "low carbon steels." The high-carbon steels are used for tools, and the low-carbon for structural purposes.

Another classification is based on the method of manufacture:—(a)—Puddled steel, made from pig-iron which has not been fused, but welded up from a pasty mass. (b)—Cement steel, made from malleable iron. (c)—Crucible cast steel. (d)—Bessemer steel. (e)—Open-hearth steel. (f)—Basic steel. The American Society of Mechanic Engineers in 1876 introduced the terms:—Weld iron, weld steel, ingot iron, ingot steel.

## Chemical Composition of Steel.

Steel is essentially a compound of iron and carbon, other constituents being regarded as accidental impurities, except in so far as they are introduced to confer special properties.

**Carbon**—The carbon content of a steel may vary between 0.1 per cent. and 1.8 per cent. or more. The grade of the steel is usually determined by the quantity of carbon present. Graphitic carbon is never present except, perhaps, occasionally in high-carbon steels. A variety of uncombined carbon known as

graphitic temper carbon sometimes separates when high-carbon steels are slowly cooled. The combined carbon exists in at least two forms:—(a)—As a definite carbide disseminated through the metal called "carbide carbon." (b)—Distributed evenly through the mass either in combination with the whole of the iron, or in solution with it. This variety is chiefly present in hardened steel, and is called "temper carbon."

**Silicon**—The general effect of this constituent is to harden and strengthen the steel, but to a much less extent than carbon. Turner says that "the increased strength due to 0.2 per cent. silicon is about 1.8 tons." Campbell states that "silicon cannot be classed among the highly injurious elements, and small quantities cannot exert a very deleterious effect, but when the percentage is very high the metal becomes very hard and brittle."

**Phosphorus** is universally regarded as the greatest enemy of the steelmaker. Up to 0.1 per cent. it increases the tensile strength, but if the metal is subjected to shock it is liable to break readily. The effect of phosphorus seems to be greater in higher-carbon than in low-carbon steels. It produces a typical coarsely-crystalline structure and it lowers the maximum temperature to which the steel may be heated in working.

**Sulphur** produces "red shortness" and gives a coarsely-crystalline fracture. The metal also tends to crack during rolling and welds badly. If manganese is present in the steel a larger quantity of sulphur is permissible.

**Manganese** counteracts the effect of sulphur, increases the tensile strength, but also increases the tendency to crack when suddenly cooled. Up to 1 per cent. it has little injurious effect on mild steel, but in larger quantities it tends to make the metal brittle under shock. The effects of nickel, tungsten, chromium, etc., are briefly considered under "Special Steels" later. The compositions of high-, medium- and low-carbon steels are as follows:—

	High carbon	Medium carbon	Low carbon
Carbon .....	1.2	0.5	0.15
Silicon .....	0.20	0.2	0.08
Sulphur .....	0.01	0.04	0.03
Phosphorus .....	0.01	0.04	0.03
Manganese .....	1.0	0.85	0.4

## Methods of Steel Making.

The method of making steel directly

from the ore is now obsolete except in the special case of the Stassano electric furnace. The process of steel-making from malleable iron is one of cementation, and depends upon the fact that if bar iron is heated for a long time at a welding temperature in contact with carbon the latter travels into the iron and the metal becomes carburised. We have to account for two changes in the material: (a)—The transmission of the carbon into the iron. (b)—The formation of "blisters."

There probably is a very slow diffusion of the solid carbon into the iron, but the usually accepted theory is that at the high temperature, and in the presence of excess of carbon, carbon monoxide is produced,  $C+O=CO$ . This penetrates into the pores of the iron, and is decomposed on contact, carbon being deposited, and carbon dioxide being produced  $2CO=CO_2+O$ . This carbon dioxide diffuses out, and is reconverted into carbon monoxide. At welding temperature the carbon combines with the iron, and steel is produced. The "blisters" are probably due to the presence of minute specks of solid impurities, such as oxide of iron. Carbon is deposited in contact with these, carbon monoxide is evolved, and the oxide reduced, the gas attempts to diffuse, and if near the surface the metal cannot resist the pressure and a "blister" is formed.

## Crucible Cast Steel.

The process of making crucible cast steel is essentially one of melting, but certain chemical changes also take place. There is always some oxide of iron in the metal and air in the pot, therefore, there is at first, at any rate, a basic silicate formed. As the action proceeds this becomes more and more acid. The composition of the metal may change somewhat, as it will pick up a little silicon from the pot and carbon from the fuel; also the mere fact of the metal being molten for some time will give opportunity for a slight oxidising out of carbon and silicon. The presence of manganese tends to prevent the removal of silicon by oxidising first, and thus using up the available oxygen. The result of melting, then, is almost always to increase the percentage of carbon and silicon and to reduce the manganese. The amount of sulphur also increases

\*From a paper read before the London branch of the British Foundrymen's Association.

slightly, either from the pyrites in the clay or from the furnace gases.

As is well known, the freshly-melted metal teems fiery and yields an unsound casting, due to evolution of gas during cooling. The "killed" metal teems quietly. According to Howe, killing probably acts chiefly by enabling the metal to absorb silicon from the walls of the crucible, thus increasing its solvent power for gas and enabling it to retain in solution during solidification the gas which it occludes when molten. The common belief is that killing expels the gas present, so that less remains to escape on pouring; but we find that silicon is rapidly absorbed during killing, and when conditions are such that the metal cannot absorb silicon, holding the metal molten does not kill.

The production of sound castings by "medicines," automatic stirring and by presses is briefly discussed later under "Casting of Steel." The most generally used "medicines" or improvers for steel are manganese peroxide, common salt, sal ammoniac, fluorspar, potassium chlorate, and, in the case of large ingots, aluminium and silicon. The processes of making steel from pig-iron may next be considered.

#### Acid Bessemer Process.

The theory of this process is the oxidising out of the impurities by blowing air through the molten metal. The plant is well known. The removal of carbon commences immediately, also silicon is similarly removed, but in the acid process sulphur and phosphorus are not removed. This fact makes it impossible to use a phosphoric iron in this process. The percentage of silicon must be at least 2.25 to 2.5 per cent., as it is the principal source of heat during the operation; but at the same time it should not exceed 3 per cent., as the metal may become too hot and too much iron may be carried away as silicate of iron. A suitable pig would be:—Graphitic carbon, 3.42 per cent.; combined carbon, 0.46 per cent.; silicon, 2.5 per cent.; sulphur, 0.05 per cent.; phosphorus, 0.03 per cent.; manganese, 0.5 per cent. Recarburising by means of spiegel for ferro-manganese fulfils two purposes:—(1)—Adding the requisite amount of carbon. (2)—Improving the metal by removing occluded oxygen.

#### Basic Bessemer Process.

As mentioned above, the acid process will not remove phosphorus. In order to do this, a basic lining is necessary, and lime is also thrown into the converter. Phosphorus is very little removed until the carbon has gone, that is, during the "after blow." The phosphorus is removed as calcium phosphate in the slag, and an important point is

that the basic slag must be poured off before recarburising, or some of the phosphorus will be reduced back again, and re-enter the iron. It is the phosphorus which provides the heat of reaction in the basic process, and the silicon should be low. A suitable pig would be:—Graphitic carbon, 0.82 per cent.; combined carbon, 2.83 per cent.; silicon, 0.63 per cent.; sulphur, 0.07 per cent.; phosphorus, 2.75 per cent.; manganese, 1 per cent. The steel can be made milder than in the acid process, but it is not considered so reliable by some engineers.

As a passing reference to the modification of the Bessemer process, such as the Clapp-Griffiths, the Tropenas, Walrand-Roberts and the Swedish, it may be said the chief difference is merely that of alteration in size and shape of the converter and the matters of side versus bottom blowing, and fixed versus rotating vessels. Small converters can never become general, but at the same time there are obviously cases where their use is advantageous. There is an increased loss of 4 per cent. in side blowing, and less uniform mixing of the metal. As to fixed converters, the time is longer, as the charge must be tapped. They do not permit of bottom blowing, and it is impossible to recarburise in the converter.

#### Open-Hearth Process.

In this process the oxidising out of the impurities is effected by means of oxide of iron. Recarburising is effected by means of ferro-manganese or carbon (the Darby process). As in the Bessemer process, the phosphorus is not removed in the acid open-hearth. In the basic process lime is added, and the lining is of dolomite, but it is not necessary to use basic bricks above the slag line. As the source of heat is external, the amount of silicon and phosphorus is not so important as in the Bessemer process.

The modifications of the open-hearth process are chiefly mechanical. The Wellman and Campbell tilting furnaces ensure, amongst other things, quicker working. The Bertrand-Thiel process consists of working two furnaces together, nearly purifying in the "primary," and finishing off in the "secondary" furnace. The Talbot process is a continuous one, part of the finished charge being tapped and fresh pig added.

The removal of sulphur by the Saniter process is effected by bringing molten steel into contact with lime and calcium sulphide, whether in the furnace or in the ladle, the sulphur passing into the slag as calcium sulphide. Sulphur is also removed to a certain extent by the use of a mixer, which may be regarded as

a reservoir for molten metal previous to steel making.

#### Electric Smelting.

Extravagant claims have been made for electric smelting, but there is no doubt that high-class steel can be made and cheap materials used, as phosphorus, sulphur, etc., are removed to a trace. Probably it will come into operation for refining materials, and in connection with open-hearth and Bessemer steel. Electric furnaces are used for making high-class steel from pure materials and from rail ends and scrap; for making special steels from open-hearth and Bessemer steel; for making ferro-chrome and ferro-silicon; for the direct production of steel from ore.

The high quality of the steel produced by electric smelting is probably due to the absence of occluded gases, the absence of over-oxidation and less segregation. Steels of highest quality, equal to the best crucible steel, can be made at a lower cost. For special steels for guns it can compete with the open-hearth furnace. For ordinary rail or structural steel it is too costly unless water-power is available. It is highly recommended for refining Bessemer and open-hearth metal. If molten metal is used, the extra cost over the open-hearth is small, and is more than compensated by the low price of the materials used.

#### Casting of Steel.

In the casting of steel there are four defects to be considered:—

(1) Blowholes.—These are due to occluded gases, carbon monoxide, hydrogen and nitrogen produced from the moisture in the air and in the materials, oxygen from the air, carbon and the constituents of the air itself. These gases cannot completely escape and are mechanically entangled in the pasty metal. An approximate analysis of a gas of this nature is as follows:—Carbon dioxide, 0.48 per cent.; hydrogen, 49.8 per cent.; carbon monoxide, 48.23 per cent.; methane, 0.40 per cent.; nitrogen, 1.40 per cent.

It is a known fact that steels of practically the same composition vary greatly in hardness, tensile strength, etc., when manufactured in different ways. This may possibly be attributable to the presence of nitrogen. Nitrogen is particularly injurious to special steels. Nitrogen and oxygen tend to produce blowholes, and sometimes they produce a peculiar kind of brittleness, due to pickling. This can be removed by annealing. The deleterious effect of these gases should be more widely recognised.

(2) Piping.—This is due to the solidification of the metal nearest the side of the mold, and its consequent contraction. The pipe is formed as an internal

cavity, usually at the top of the ingot.

(3) Segregation.—By segregation is meant the separation of the metal into portions of different composition during solidification. Steel is not a definite chemical compound, and therefore the less fusible constituents solidify first. There is a tendency for pure or nearly pure iron to separate first. In ordinary ingot casting the segregation is not large. In a plate ingot 10 in. thick the carbon may vary from 0.18 per cent. at the top to 0.15 per cent. three inches from the bottom, and the phosphorus from 0.075 per cent. to 0.058 per cent. in the same limits.

(4) Cracks.—These are produced by the expansion of the mold and its drawing away from the metal. If not sufficiently plastic to follow, the metal will crack. The unequal contraction of the external and the internal portions of the ingot may also produce a fracture.

#### Prevention of Defects in Cast Steel.

**Mechanical Pressure.**—This involves the use of a press, such as the Whitworth, Illingsworth, or Harmet. In these the contraction of the metal is followed up; it is really casting under pressure.

**Agitation and Centrifugal Force** is another method which has been tried.

**Chemical Methods.**—The two substances usually employed to prevent defects are aluminum and silicon. The action of silicon is very marked, and entirely removes blowholes, the explanation probably being the same as that given under "killing" of crucible cast steel. The action of aluminum is quite as marked, but the rationale of the action is less understood. It may be due to the fact that aluminium removes oxygen, and as oxygen diminishes the solubility of the gases in iron, the aluminium may thus indirectly raise the solvent power.

**Special Molds.**—The principle involved in the use of special molds to prevent the defects mentioned is to make the lower 70 to 80 per cent. of the mold thicker, and therefore of greater heat absorptive capacity than the upper 30 per cent.

#### Special Steels.

There has been a great advance made of late years in the manufacture of special steels. The following notes relate to the effects of the special constituents introduced:—

**Nickel Steel.**—The tensile strength increases with the percentage of nickel. Thus 0.3 per cent. nickel gives a tensile strength of 31 tons, whilst with 11.4 per cent. it is 65 tons. The elastic limit increases more rapidly than the ultimate strength. Nickel steel has a high vibrating strength, and is more rigid and tough than ordinary carbon steels. The recalescence point is lower, the annealing temperature is lower, and the metal hardens when quenched from a lower

temperature. It resists corrosion, and possesses a high electrical resistance. It loses its magnetism when heated, but regains it when cooled. Nickel 3.5 per cent. has about the same effect on tensile strength as 0.2 per cent. carbon. Other constituents being constant, 0.8 per cent. and from 3 to 5 per cent. nickel gives a good tool steel.

**Manganese Steel.**—The effect of manganese is to harden the metal as the percentage of manganese increases. Up to about 5 per cent. manganese the metal is very hard, while over 7.5 per cent. it becomes hard and tough. Hadfield's manganese steel has a tensile strength of 67 tons, and the metal is ductile. The electrical resistance is very high, and it is non-magnetisable.

**Chromium Steel.**—The chief property that chromium confers on steel is that of hardness; hence its use in armour plate and projectiles. Five per cent. chromium will give a tensile strength of 74 tons unannealed.

**Tungsten Steel.**—Tungsten makes the steel intensely hard, and this hardness is not reduced by slow cooling. Tungsten steels are not hardened by heating and quenching, hence the name, "self-hardening steels." These steels are much in favour as tool steels. An average composition is 1.5 per cent. carbon and from 6 per cent. to 9 per cent. tungsten, although lower percentages are now common. Under this heading may be mentioned a special steel the composition of which is as follows:—Carbon, 0.55 per cent.; chromium, 3.5 per cent.; tungsten, 13.5 per cent.

**Molybdenum and Vanadium** are used in special steels, the latter especially in some American tool steels. They have a still greater proportionate effect than those elements mentioned previously. A typical analysis of an American molybdenum steel is:—Molybdenum, 9.65 per cent.; carbon, 0.66 per cent.; manganese, 0.22 per cent.; phosphorus, 0.02 per cent.; silicon, 0.05 per cent. Many molybdenum steels have a lower percentage of Mo. From 0.5 to 3 per cent. of molybdenum in a high tungsten steel slightly increases the cutting efficiency.

**Vanadium Steel.**—Vanadium raises the elastic limit and tensile strength, but slightly reduces elongation; 0.2 per cent. vanadium added to a low-carbon steel raises the elastic limit and tensile strength 50 per cent. or more. This steel is valuable for engine parts and details subjected to alternating stress. It hammers and welds well. A steel containing 0.24 per cent. carbon, 0.28 per cent. vanadium, and 3.38 per cent. nickel gave the following results:—Elastic limit, 50.3 tons; tensile strength, 68.2 tons; elongation, 17 per cent.

It must be pointed out that the fore-

going figures are general and are much affected by the percentage of carbon and by the heat treatment.

#### Hardening of Steel.

When a steel containing more than about 0.2 per cent carbon is heated to redness and quenched it becomes hard. The degree of hardness depends on the rapidity of the cooling, temperature of cooling and percentage of carbon. The changes observable are:—Pure iron heated to about 900 deg. C. and cooled slowly shows three distinct retardations, viz., at 825 deg. C. ( $A_r$ ); 720 deg. C. ( $A_r$ ); and 650 deg. C. ( $A_r$ ). If much carbon is present there is only one point discernible, viz., at 670 deg. C. ( $A_r$ ). If iron is heated, three corresponding points are got, about 30 deg. C. above the  $A_r$  points, namely,  $A_c$ , and  $A_c$ , and  $A_c$ . The retardation at  $A_r$  is accompanied by a change in the condition of the carbon from hardening carbon as it exists in hardened steels to cement carbon ( $Fe_3C$ ), which is present in normal and annealed steels. To convert cement carbon into hardening carbon it is necessary to heat above the critical  $A_c$ .

If the steel is heated above  $A_c$  (700 deg. C. for 12 per cent. steel), and quenched, the carbon is retained as hardening carbon. When a steel is heated to  $A_c$  and quickly or slowly cooled, the finest grain it is capable of assuming is produced. If heated above  $A_c$  the grain becomes coarser and coarser. The best temperature to quench from is that temperature which gives the finest grain and the greatest strength, and this depends on the percentage of carbon.

#### Annealing.

The object of annealing is to diminish the abnormal qualities the metal acquires through hardening and mechanical working. The metal should be annealed by heating to the  $A_c$ , critical temperature, and keeping at that temperature a sufficient time to change a certain amount of the hardening carbon into cement carbon or the hard into the soft allotropic variety of iron. It is immaterial whether it is quickly or slowly cooled. The heating should be slow, and the steel throughout the operation should be shut off practically from the air. The time occupied in actual practice is variable, and whilst there can be no doubt that excessive annealing does no good, and may do harm, a good proportion of the unsatisfactory steel castings is accounted for by erring on the other side.

The typical structure of a normalised steel of 0.5 per cent. carbon consists of ferrite and pearlite. (Pearlite is  $Fe_3C$  in intimate association with Fe and contains 0.9 per cent. carbon.) The amount of each constituent depends on the percentage of carbon. The structure is

typical of a mild steel, which after being heated to full redness is allowed to cool in the air. A saturated steel contains 0.9 per cent. carbon, and the structure is all pearlite. As the percentage of carbon increases beyond this point, a new constituent appears, viz., cementite,  $\text{Fe}_3\text{C}$ , which is typical of super-saturated steels.

In a hardened steel there occurs a new constituent, hardenite, accompanied by ferrite in mild steel, and cementite in super-saturated steels. Hardenite is probably pearlite altered by heating and quenching. If a steel is suddenly quenched from 1,000 deg. C. the typical needle structure of martensite is got. Annealed steels show the granular pearlite altered into parallel layers. This banded structure is true pearlite and is typical of slowly-cooled steels.

#### Defects Produced by Hardening.

**Water Cracks.**—These are the direct result of enormous stresses produced by contraction. The only remedy is to exercise the greatest care and to have a good quality steel. The steel should be low in phosphorus and manganese; 0.025 per cent. phosphorus is permissible, 0.4 to 0.5 per cent. manganese in mild steel, and 0.2 per cent. manganese in 1 per cent. carbon steels. The whole of the tool should be at a uniform temperature, and the temperature should be the correct one for the percentage of carbon present . . .

#### Special Methods of Hardening.

The Barium Chloride Bath is used for taps, etc. The bath is heated to 1,200 deg. C. by gas, and the tool is soaked for a few minutes only, so as to heat up the edges. The tool should then be withdrawn. Electric Furnace methods employ as the heating medium barium chloride for high-speed steels, barium chloride and potassium chloride for carbon steels, and sodium chloride and potassium chloride for lower temperatures. The current is alternating, and iron electrodes are used. The table given below may be interesting to show the effect of annealing and hardening and tempering on gun steel of different carbon contents:—

Carbon %	Unannealed		Annealed	
	Tensile strength Tons	Elonga- tion %	Tensile strength Tons	Elonga- tion %
0.37	38	8.2	36.7	21.8
0.5	44.4	2.0	44.0	12.0

Carbon %	Tensile strength Tons	Annealed Elastic limit Tons	Elonga- tion %	Hardened and Tempered	
				Tensile strength Tons	Elastic limit Tons
0.35	34.4	17.6	27.0	48.9	29.1

#### Case Hardening.

The ordinary methods of case-hardening are too well known to need description, but perhaps one or two points may be of interest. The best carburising

steels are those containing from 0.1 to 0.2 per cent. carbon. Manganese has the tendency to make the carburising surface brittle. The outer skin will usually come up to about 0.9 per cent carbon. As a general rule, anneal after carburising to destroy crystallisation in the core. The limit for the requisite temperature during this operation is about 925 deg. C. Carbon begins to penetrate at about 700 deg. C.

There are many special case-hardening mixtures. Guillet used 60 parts of wood charcoal to 40 of barium carbonate. Heathcote mentions wood charcoal soaked in a 5 per cent. solution of sodium carbonate. The annealing of the castings should be at a cherry red. To ensure refining of grain, the heavy sections will require a longer time for annealing, but they may be cooled quickly if high-tensile strength and elastic limit is required.

#### POWER TRANSMISSION BY LEATHER BELTING

By R. T. Kent.

THE most satisfactory belt drive is that which will at all times transmit the necessary amount of power and at the same time cost the least for repairs and maintenance, and cause the least possible loss by machine shut-downs for the purpose of making belt repairs in working hours.

To have a satisfactory belt drive the following considerations must be taken into account when the drive is laid out: The conditions of use of the belt, whether it is readily accessible or not; the velocity at which the belt will travel; the arc of the pulley with which the belt is in contact; the tension per sq. in. of cross section under which it is first placed on the pulleys; the tension per square inch of cross section to which the belt may be allowed to fall in service before it is taken down and retightened.

#### PLACE OF SCIENCE IN EDUCATION

IN considering "The Place of Science in Education," Dr. J. A. Fleming, Professor of Electrical Engineering in University College, London, recently remarked that in some schools a great show is made with carpenters' or engineering workshops. "This," he said, "impresses parents and attracts boys with a mechanical turn of mind, but there is little

or no real scientific training in it. The making of a model steam engine is an amusement for leisure hours or wet holidays, but is perfectly useless as a means of scientific education for boys.

The school work should be confined to imparting a really practical and thorough knowledge of elementary principles of science.

"Of course, in all this the quality and kind of teaching given is the important factor. The mode in which a subject is taught is even of more importance than the subject itself. Chemistry can be so imperfectly taught as to be of little use as a mind-training. It is possible to give a very scientific lesson on a Greek verb, and also to give a lesson on an electrical machine which is not scientific teaching at all. Hence here, as elsewhere, the man counts for more than the machine or apparatus. Nevertheless, the good teacher is wasted unless he has the necessary appliances."

#### SMALL FIRMS AFTER THE WAR.

IN the course of a recent discussion before the Birmingham Section of the Institute of Metals on the "Future of the Metallurgical Industries," Professor T. Turner remarked that Birmingham was not a smelting centre; it was particularly a metal-using centre. There were in the city and district 20 metal workers to every one metal maker, and perhaps the proportion was much larger. The business had grown up from very small beginnings, the result being that at the present time there were in the city 350 brass-casting firms. The consequence of having so many had been that organization was defective; there had been a great deal of competition, and the amount of scientific knowledge and guidance had been nil. He could not recall a single firm in the Birmingham district that dealt in brass casting alone that had a scientific adviser or even an analyst.

In the future, he considered, big concerns would be the rule. The small firm could not make a big gun, nor undertake the manufacture of aeroplanes, nor the construction of a battleship. There would be a combination of the small firms, or they would be squeezed out. It must be through big firms that some of the work that was absolutely essential for the country would be done, and it was firms like those that could afford to pay adequate salaries to their officials, obtain scientific advice, and conduct researches. It was by the combination of organization and scientific knowledge that success could be obtained. It seemed to him we must provide for the smaller firms, for, if we did not, obviously we could not have the big firms. The smaller firms would pay attention to specialties, but it would be by big firms that the greater part of the work of the nation would be done.

# Machine Tool Building in a General Manufacturing Plant

## Staff Article

*The past two years have been full of opportunities for the machine shop proprietor, but in order to derive the full benefit it has been necessary to fore-see to a great extent just what the impending requirements of the situation would be. The successive manner, in which the types of machines referred to have been produced, bears evidence of that wide knowledge of supply and demand which is a pre-requisite to success in any line of business.*

IN days to come, when the efforts of the Dominion are viewed with a true perspective, the value of the assistance rendered by the smaller machine shops to munitions manufacturers will become more apparent. There are few shops indeed throughout the country but what have been more or less affected by events, and while the nature of things pointed to large establishments with unlimited facilities and resources as the best ultimate producers of shells, it must not be forgotten that many of the special machines now assisting so ably in manufacturing the output of munitions were evolved and built by firms of more or less modest pretensions. One of the outstanding examples of this class is the Gray Mfg. & Machine Co., Toronto, who have up till now developed no less than four separate types of special shell machines and such supplementary apparatus as sand blast equipment, etc. Taken in order of evolution, these machines produced by this firm form an interesting record of the development of munitions

machines, the order of their origination, and gradual growth in capacity paralleling the various developments of shell manufacture during the past eighteen months. The whole course of the firm's

### War-Time Product.

Commencing with cutting off machines and proceeding through the entire range of machining operations the attention of the firm was consecutively devoted

FIG. 2. DETAILS OF GROOVE-FORMING ATTACHMENT FOR SPECIAL SHELL LATHE.

activity is evidence of close attention to; and careful analysis of the numerous problems of shell manufacture.

to cutting-off machines, thread millers for small shells, thread millers for large shells, and a special shell lathe adapted to perform all the principal operations on shells up to 9.2 in. dia. By thus confining their activity principally to straight machine building, the immediate no less than the ultimate effect of their efforts, was of much greater benefit to munitions output than if actual shell making had been undertaken, especially at a time when machine tools were scarce.

With the gradual completion of equipment by shell shops, production of machines for preliminary operations has to some extent declined hence the present demand for later operation machines such as thread millers and lathes for various operations.

### A Special Lathe.

The special shell lathe shown in course of construction in Fig. 1, is designed to handle large shells up to 9.2 in. diameter, and by means of various attachments will do work as follows: 1st., cut off and turn; 2nd., bore out the interior; 3rd., finish turn the parallel body and form the nose profile; 4th., band groove forming. The belt drive is direct from line shaft to a 20 in. dia. by 9 in. face pulley mounted on a friction clutch capable of transmitting 30 horse-power. Double reduce-

FIG. 1. SPECIAL LATHE FOR LARGE SHELLS IN COURSE OF CONSTRUCTION.

tion gears with a ratio of 9 to 1 transmit the power from the pulley shaft to the spindle, the spindle gear having 4-in. width of face and located directly behind the front bearing. The headstock is cast integral with the bed, and has adjustable babbitted bearings, the front one being  $9\frac{1}{2}$  in. diameter by  $9\frac{1}{2}$  in. long and the rear 6 in. diameter by 8 in. long, sight feed oil cups being provided on both bearings.

The front way of the bed is of heavy Vee section, the rear way being flat, while the carriage is of liberal proportions and simple construction. The carriage is fed by a  $1\frac{3}{4}$  in. 4 pitch screw working through a long nut in the apron and having a ball thrust bearing. Hand traverse is by handwheel in the centre of apron, this not being assembled yet in the illustration. At the far end of the feed screw may be seen a bracket projecting from the bed. An extension of the feed screw shaft is carried in this boss, and has mounted on it a clutch and pulley. The pulley is belted to the line shaft and the clutch which is operated by a sliding shaft and hand lever seen on front of the headstock, may be engaged alternatively with the pulley or the feed gear. In the case of the pulley, a quick return of the carriage to its starting position is obtained, the feed gear being inoperative during this time and until the clutch is engaged with it. The sliding clutch shaft is extended to the carriage and is provided with knock-out stops for auto-

Thus for cutting off and rough turning the shell forging, a heavy duty tool rest of the European type is pro-

the parallel portion while the other is controlled by a profile cam mounted on the back of the lathe bed, each tool be-

FIG. 3. THREAD MILLER FOR LARGE SHELLS UP TO 9.2 IN. DIAMETER.

vided for the turning operation, while overarms, operated by a cam on the carriage carry the parting and facing tools. The shell is supported on an arbor and tail centre, being located from the inside of the base and driven by automatic dogs in the arbor.

When being bored, the shell is held in

ing separately adjustable by a feed screw with graduated collar.

#### Grooving and Waving.

The band groove forming operation is performed by the attachment shown mounted on the bed in Fig. 1, and also in detail in Fig. 2. A stationary tool carriage A is clamped to the bed, clearance on the underside allowing the regular carriage to approach closely. On the front of this stationary carriage are two divergent slides carrying the under-cutting tools, while at the rear is the waving tool reciprocating horizontally in a slide formed in bracket B, which in turn is fed into the work along a slide on the stationary carriage. Feed motion to the various tools is derived from cam rods C and D attached to sliding carriage.

A positive gear drive conveys motion from the spindle to the waving tool in the ratio of 8 reciprocations per revolution. The shell bodies, with the groove previously roughed out are inserted nose first in chuck F, the nose being centred in a spring supported socket or bushing while the outer end is supported by the tail centre. The spring allows the shell to be adjusted with the groove opposite the tools, being then driven by a floating driver G on the outer end of the chuck. The back end of the chuck has a gear rim, driving through gears and shafting as shown to the cam actuated block in slide B. The shafts are feathered in the small level gears to allow longitudinal adjustment to all of the tools, and a liberal feed travel to the waving tool, independent adjustment of

FIG. 4. DETAILS OF THREAD LEAD DEVICE ON THREAD MILLERS.

matically stopping the carriage travel at either end.

#### Variety of Equipment.

As already mentioned suitable equipment is provided for various operations.

a suitable chuck while a turret with 24 in. diameter of base carries the boring bars, a sensitive hand feed with star wheel being provided.

Profile turning is accomplished by using two tool rests, one operating on

course being provided for each tool. A heavy tailstock of standard type with No. 5 Morse taper centre is part of the equipment which includes pump, gear covers, etc.

#### Thread Miller.

Illustrated in Fig. 3 is the larger of two designs of thread milling machines capable of handling all sizes of shells, sockets and plugs, up to 9.2 in. The larger machine as shown is equipped for threading 8 in. shells, and in common with the smaller machine it consists of a work carrying headstock with lead screw device for controlling the pitch of the thread, while the cutter-head is mounted on an adjustable carriage gibbed to the warp on the bed.

When it is considered desirable, as is frequently the case, to face the work in addition to threading, a cutter holder is mounted on the carriage in front of the milling cutter, the carriage then being used in the same way as an ordinary lathe carriage using the two handwheels for controlling the tool. By the addition of suitable chuck parts, this machine will thread bases as well as other parts.

In order to handle the large shells the construction of the spindle is as shown in Fig. 3. This consists of an extension which embraces the outer end of the shell and is supported in a suitable bearing, the other end resting in the rear bearing, on the outside of which is assembled the driving gear and the lead screw device. Underneath the headstock is located the driving gear which provides two separate speeds for milling and facing, the ratio being 90 to 1. Considerable interest attaches

to the yoke C, which is stationary it acts as a nut, causing sleeve B and thereby the spindle to travel through and give a lead to the thread being milled in the work. If, however, it be desired to do facing on the work, the yoke C must be locked to the spindle

FIG. 5. TWO-SPEED GEAR DRIVE ON THREAD MILLERS.

and revolve with it, the thrust bearing referred to preventing any lengthwise movement of the spindle.

The locking of the yoke as described is accomplished by the handle on the lower end. This handle is attached to a small gear, on opposite sides of which are two locking pins with rack portions meshing with the pinion. When moved to the right side the short pin engages with bearing D and holds the yoke stationary. When moved to the left side it disengages the short pin and engages the long pin with the sleeve thus locking the yoke to the sleeve. When in the neutral position, both pins are disengaged so that the yoke may be turned around backwards by hand and the spindle travelled along till the sleeve is backed through the yoke again. The length of travel provided on the sleeve is sufficient to allow of a considerable

a worm and a bevel gear. The worm gear is above the worm. It is loose on its shaft and revolves continuously, and imparts motion to the shaft when the clutch is engaged by the hand lever on the outside of the head. Through the

medium of a bevel and spur gear, motion is imparted to a pinion at the left-hand end of the clutch shaft, which also revolves continuously and is engaged with the opposite side of the clutch when the facing speed is wanted. The low speed is used when milling the thread. From the clutch shaft, the drive is conveyed by a suitable train of spur gearing to the rear end of the spindle.

#### Chucking Large Shells.

The method of inserting shells in the large machine is rather novel and possesses the merit of simplicity combined with accuracy and reliability. As shown in sketch Fig. 6 the extended spindle is cut away on two sides leaving a space through which the shell is lowered. When moved to the right, the base of the shell comes in contact with a hardened steel ring, the bore of which is slightly coned so as to centre the shell at this end. The opposite end of the spindle is bored out parallel to receive a flanged disc, fastened to a hollow stem which fits in a hole through the spindle. The stem is threaded on the inside, forming a nut which fits on the threaded end of a rod operated by a handwheel at the tail end of the spindle. By this means the flanged disc is drawn back into the spindle when inserting the shell, after which it is moved forward till three formed jaws on it come in contact with the shell nose and locate it centrally thus insuring a concentric and parallel thread being milled in the base end. The outer bearing is adjustable for wear, a split taper bushing being provided for this purpose.

FIG. 6. OPEN SPINDLE FOR LARGE SHELLS.

to these two devices the lead screw device being shown in Fig. 4 and the two speed gear in Fig. 5.

#### Thread Lead Device.

Referring to the former, A is the tail end of the spindle on which is keyed a sleeve B, threaded on the outside to fit the threaded bore of yoke C. Yoke C is retained in position by bearing D attached to the end of the bed, a thrust washer and lock nut being provided as shown. When the yoke C is held sta-

tionary it acts as a nut, causing sleeve B and thereby the spindle to travel through and give a lead to the thread being milled in the work.

#### Two-Speed Spindle Drive.

The arrangement of the two speed gear is simple and compact and of substantial proportions for the work it has to perform. Fig. 5 shows the front and end elevations the belt pulley on the worm shaft being behind the headstock and not seen in Fig. 3. The portion of the driving shaft inside the bed carries

#### Regular Output.

The normal products of the Co. include several types of power pumps suitable for boiler feeding, fire, hydraulic-elevator and general service. They include piston and centrifugal pumps and also duplex and triplex

power pumps are suitable for a working pressure of 150 lbs. per sq. in. the former machine being illustrated in Fig. 7. Four sizes of this pump are marketed from 4 in. x 6 in. to 6 in. x 10 in., the capacities varying from 100 to 275 gals. per minute, and either direct motor drive or belt drive as shown.

A ball bearing duplex power pump for water supply systems is shown in Fig. 8, the pump having a capacity of 400 gals per hour against 80 lbs pressure. They are equally well adapted for motor or engine drive and being equipped with ball bearings require a minimum amount of attention and power.

Grinding and polishing machinery for foundry and general use forms another branch of activity, one of the latest types of buffing and polishing lathe being shown in Fig. 9. This is a double spindle lathe, each spindle being independently driven so as to allow of two workmen obtaining the maximum output without delay due to stoppage of either spindle. The drive is from the floor, allowing the frame to be completely enclosed so as to give maximum protection to belts and bearings. It is built for severe service and weighs 900 lbs.

mission which, immediately prior to the outbreak of war, was completing a tour of the Overseas Dominions and making

Langerman, South Africa; Sir Edgar Bowring, Newfoundland.

F. C. T. O'Hara, Deputy Minister of Trade and Commerce, is the local officer of the Commission. When war broke out the sittings of the Commission in Canada had just begun, the cities of Halifax and St. John having been visited. When war was declared the Canadian programme was cancelled and the Commission returned to England. The arrangements which had been made for sittings in various parts of Canada for the calling of witnesses, etc., will now be put into effect, the necessary instructions having been issued

FIG. 8. BALL-BEARING DUPLEX POWER PUMP AND WATER SUPPLY SYSTEM.

a study of the resources and industrial and economic conditions and possibilities with a view to Imperial trade expansion on systematic lines.

The commission consists of Lord

this afternoon. The Commission will begin its sittings on the Pacific coast.

#### FRIENDSHIP IN BUSINESS

AN open friendship between employer and employee—the individual friendship between a manager or superintendent and each of his men—is of great value to a business. It begets a loyalty that nothing else can. A man once said to me, “Whenever I feel a little blue I go and have a talk with Mr. Smith, our manager, and I come out feeling fine. We may not talk about what I had in mind, but I feel encouraged just the same.”

I had often heard of Mr. Smith's success with his business and with his men, and this seemed a fair explanation of that success. Such an interchange of friendly confidence brings out the best there is in the men—or shows what they lack. It enables a manager to get in touch with the ruling motives of his men, and to learn how each individual should be treated in order to get the best results.

#### A WOMEN'S ENGINEERING WORKS

AN experiment of a quite novel kind is about to be tried in Scotland. Everyone has heard of the excellent work which women have done during the last year in munition works and elsewhere, but this work has been done, largely at all events, in factories in which there was a greater

FIG. 7. DUPLEX POWER PUMP ARRANGED FOR BELT DRIVE.

**DOMINIONS ROYAL COMMISSION.** THE Dominions Royal Commission will meet in Canada on September 21 next. Word to this effect has reached the Government by cable. This is the com-

D'Abernon, chairman; Sir Alfred Bate-man, Sir Rider Haggard and Messrs. Lorimer, Garnet, Tatlow, of the United Kingdom; Sir George Foster, of Canada; Mr. Sinclair, of New Zealand; Sir Jan

or less admixture of men workers. In the present experiment, which we understand is to be financed by two of the directors of a well-known controlled firm, all the workers are to be women, and the establishment is not destined only to be run during the continuance of the war, but to continue permanently.

The actual site of the works has not, as far as we are aware, been as yet publicly announced, but it is understood that it will be "somewhere on the West Coast of Scotland." The works themselves, which are to be run on novel and interesting lines, will be open only to well-educated women between the ages of twenty and thirty-five, who show a bent for mechanics, and in choosing the workers, preference will be given to widows and daughters of officers in the army and navy.

One feature of the working of the scheme is that the amount of remuneration given will be decided by means of examinations. The first six weeks are to be regarded as a probationary period, during which payment will be at the rate of \$5 per week. At the conclusion of that time those who have shown that they have not got the necessary mechanical instinct will be told that they cannot remain at the works, and with those who have shown evidence of possessing this attribute, agreements will be made for them to work for certain periods. The examinations are to be held at the end of each six months, and on the result of

these the wages are to be gauged. The actual amounts to be paid are not yet definitely settled, but it is apparently probable that the lowest will not be less than 25s. per week, and that as much as £250 a year may be reached.

Another feature of the scheme is the

operation in the early autumn, and, at first, it is intended that the work undertaken shall be the production of parts for aeroplane engines. Later on it is hoped to turn out complete aeroplane engines.

#### MILLING FIXTURES FOR H.E. SHELLS

IN the latest designs of high explosive shells, there are three nicks cut in the fuse seat, the object of these being to provide a means of holding the fuse in position by burring over the edge of the fuse into the nicks. In consequence of this, the  $\frac{1}{4}$ -inch grub screw which previously served this purpose is now dispensed with. These nicks can be cut either by filing, by shaping, or by milling, but undoubtedly the greatest production will be obtained by the last method.

As the work is not heavy, it can be done on a comparatively light horizontal milling machine, the only difficulty being

the provision of a suitable fixture. One of three types of fixtures will be required, for nicks may be cut in the brass fuse which is sometimes used for bottled shells; alternatively, they may be in the loose steel heads which occur in some designs; or lastly, they may be in the shell itself when this is of the bottled type and no loose bush is employed. To handle this work economically, Alfred Herbert, Coventry, England, have designed a line of fix-

FIG. 9. DOUBLE SPINDLE POLISHING LATHE WITH FLOOR DRIVE TO SPINDLES.

arrangement of the working day. There will be a night and day shift, each shift being divided into two periods of four hours each. The interval between the two halves of the day shift will be two hours long and during one quarter of it technical instruction will be given in classes which will have to be attended by those in their probationary period, though attendance will be optional for those who have passed it.

The factory will, we believe, be in

FIG. 10. VIEW OF MACHINE SHOP WITH WORK IN PROGRESS.

tures for use on horizontal milling machines, these being indicated in outline by Figs. 1-2-3.

FIG. 1. TYPE "A" FIXTURE FOR 4.5 IN. SHELLS.

#### Type "A" Fixture.

This fixture, Fig. 1, is used for the brass bushes. It is a vertical dividing fixture provided with a curved-in index plate and plunger. The bush is located by a vertical stud, fitting into the plain bore, and is clamped by a washer and nut. The washer has three slots cut in it to clear the milling cutter, one of these slots going right through to the centre to make the washer easily removable. The part of the stud which fits into the washer is formed to a special shape, so as to ensure the slots coming in the correct position in relation to the index plate. In cutting the nicks, the work is fed in the direction of the arrow up against the milling cutter, the fixture being indexed into three successive positions. The heights of the milling cutter is so arranged that the tangent at the point of contact with the work gives the correct inclination to the nick, and it will be seen that the nicks cut in this way have a slight radius left at the bottom. This point was taken up with the authorities when these fixtures were being designed, and they state that no objection will be taken to this slight curvature. A fixture to produce a straight bottom would have to be inclined at the correct angle, in order to traverse the nick completely, and this would entail a much more awkward fixture than is necessary by the method described.

#### Type "B" Fixture.

This fixture, Fig. 2, is used for the loose steel heads, and is very similar

to the type A fixture, except that it is of course larger. The method of locating and clamping is the same.

#### Type "C" Fixture.

When the nicks have to be cut in the shell itself, a horizontal fixture must be used, as shown in Fig. 3. This fixture consists of a hollow spindle in which the shell is clamped by a set screw, the part to be nicked being pushed on to a fixed locating peg cut away on one side to clear the milling cutter. The spindle

FIG. 3. TYPE "C" FIXTURE FOR 4.5-INCH SHELLS.

is provided with an index plate and plunger, the shell revolving on the locating plug during the indexing. This type of fixture is again designed so that the nicks have a slight curvature at the bottom, and the arrangement is very compact, for a fixture designed to cut

FIG. 2. TYPE "B" FIXTURE FOR 4.5 IN. SHELLS.

a straight bottomed nick would be of considerable height.

In all three cases the stop on the machine table should be set to limit the

travel of the work, so that all nicks will be the same depth.

These fixtures are applicable to shaping machines provided they are mounted on suitable angle plates, and can also be used on lathes by mounting on the cross slide, the milling cutter being run on a mandril between centres

### FEAR OF DISMISSAL

THOUSANDS of men and women are living in constant fear of losing their

positions. It is good to know that, in most instances this fear is groundless, but until this fact is known to the worker he is just as unhappy as if the danger were real—perhaps more so than if he actually had been dismissed.

This fear is so blighting in its effects, so detrimental to good work, that employers and managers and all with any degree of authority in business should take every reasonable precaution to remove it from the minds of employees. When necessary to quiet the thought of a fearful employee, it is sometimes well for the superior to come right out with the assurance and say, "Don't be afraid of losing your position with us; we need you and are depending on you to help us carry on this business." Such an assurance is of untold value to a worker, not only to his peace of mind but also to his work itself.

Some employers and managers try to rule their men by purposely keeping them in fear of losing their positions. Such a policy is nothing short of cruelty. A manager who knowingly does that, has no moral right to hold authority at all. This policy should be utterly condemned wherever found. It may sometimes be done ignorantly, but the effect is the same as if done from cruel motives.

Let every sincere worker feel the satisfaction of knowing that his efforts are appreciated, and that he is not to be cast aside at the whim of any man.

The Dominion Copper Products Co. has increased its capital stock to \$1,000,000.

# PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

## GATE VALVE RESEATING MACHINE

**T**O maintain the highest operation efficiency in any make of valve, the latter must have a perfect bearing on its seat to reduce to a minimum any possibility of leakage. Owing to the peculiar construction of gate valves, it is very difficult—without the aid of special equipment—to maintain them in good condition. To remove the seats from their fixed position requires considerable time and dexterity, often necessitating delay in the operation of the plant. However, mechanical appliances are constantly being designed and

tion secured to the body of the valve while the cutters are operating on the interior valve seats. Fig. 2 is a view of the machine, in position, facing off a gate valve seat, while Fig. 3 illustrates the disc cutting device in operation. The various cutters are placed at different angles in relation to their travel, thus practically eliminating the possibility of chatter when cutting. The circular head which carries the cutters is operated by means of a flexible cable that grips the outer surface when moved in one direction, and releases when moved back again. By this method the cutters are forced to move continually in one direc-

ished in ratings up to 10 h.p., either shunt or compound wound. For a general manufacturing drive, such as for

FIG. 1. COMPLETE GATE VALVE REFACING OUTFIT.

constructed which are gradually eliminating the difficulties incidental to water and steam valve operation.

The accompanying illustrations show the Dexter Gate Valve Re-seating Machine, as recently improved, for the more efficient handling of gate valve repairs. Fig. 1 shows a complete re-facing outfit. The part to the left indicates the rigid construction of the valve disc facing device: the base plate being supplied with four adjustable jaws for holding the work, while the facing tool is carried on the end of a revolving spindle. This spindle, as well as the device in which it operates, is similar to those used in the globe valve facing attachment. The section in the centre of the cut is the por-

tion, and can be operated successfully even when the lever has only a short travel.

## D. C. MOTORS OF LOW HORSE POWERS

TO meet a demand for direct current motors of the smaller horse powers for direct connection to and driving all kinds of industrial machinery, machine tools and other applications requiring a low-power compact machine, the C & C Electric & Mfg. Co., of Garwood, N.J., has developed a new line of specially designed motors.

They are known as Type IB, are bipolar with interpoles, and can be furn-

does not greatly exceed full load torque. The compound wound motor is desirable for drives where the starting torque is

FIG. 2. FACING-OFF GATE VALVE SEAT.

machine tools and other industrial machinery, the characteristics of the shunt wound motor are the most desirable. It is essentially a constant speed machine, having close speed regulation from no load to full load, and is recommended for all purposes where the torque required for starting and accelerating

FIG. 3. DISC CUTTING DEVICE IN OPERATION.

much heavier than the full load torque. This motor starts at a much heavier load than does the other, and any degree of compounding can be furnished to meet conditions.

THE I. B. ARMATURE

The materials entering into the manufacture of these motors and their design are such as to make a compact machine, sturdy both electrically and mechanically. The main frame and supporting feet are cast integral, the pole pieces being separate. The main pole pieces and pole shoes are laminated. The interpole pieces are separately cast and the coils are all form wound. The pulley side bearing bracket is provided with a wide apron to protect the winding from mechanical injury, and the bearing supported by four arms with large openings between, makes a rigid open bracket, permitting free and ample ventilation. The commutator side bearing bracket has four arms, giving also a rigid bracket and free access to the commutator and brushes. Both brackets fit in a recess in the main frame, insuring thorough and rigid alignment.

The armatures are of standard design with laminated core. An air agitating fan is placed on the pulley side of the shaft next to the armature winding

addition of interior commutating poles forms another desirable feature. In continuous operation for long periods, these motors have been found to run cool and without attention. The interpole poles make possible sparkless commutation through the full range of load without changing the brush position.

This new line of motors is furnished

furnished with either a universal slide rail base or a belt tightener idler pulley.

### SELF - CLEANING TRAVELING WATER SCREENS

THE necessity for clean circulating and boiler water in power plants has become so much of an accepted fact to-day that it is not necessary to make explanation of it in order to introduce the subject of screens for screening this water. Ever

SELF-CLEANING TRAVELING WATER SCREENS

C & C TYPE I. B. MOTOR WITH UNIVERSAL BASE

MAIN FRAME WITH FIELD AND COMMUTATING POLES

to furnish the high degree of ventilation and cooling so necessary in motors of small compact frame, guaranteeing severe service and heavy overloads. The

in the open type, or with perforated or totally enclosing covers for protection against dust, metal chips, dampness, etc. For belt drive the motors can be

since water has been used for this purpose there have been various devices for screening it and removing at least the larger pieces of foreign matter. These

devices have ranged from an ordinary grating placed in the pipe or channel to quite elaborate and finished machines.

In all of the known methods of screening the water, however, the screens themselves require attention sooner or later. This attention meant, in some cases, a great amount of labor and difficulty, and the screening of some of the devices was more or less ineffective, principally at times when cleaning was in progress.

Every engineer is familiar with the fact that no matter how many sliding screens are placed in an intake one after the other, when each screen is raised a certain amount of sediment drops down and passes under it and on to the next one. This process repeats itself until the last screen is raised and then the droppings enter the intake to the power plant and are carried into the pumps and condenser tubes where they hasten the necessity for cleaning these auxiliaries.

It was with a view to improving the conditions outlined above that a few years ago the Chain Belt Co., built three machines known as the "Chain Belt Self Cleaning Traveling Water Screens." These were installed at the northwest plant of the Commonwealth Edison Co. in Chicago.

The accompanying illustration shows the original three screens which have been in continuous operation since their installation.

The early experience of the Chain Belt Company has enabled them to make many improvements and developments in the mechanical design so that the screens built at present are quite different from the original installations. The machines consist essentially of wire screening baskets mounted on two strands of steel chain belt. These chain belts and screens form a continuous screening apron which passes over sprockets at top and bottom of the device, and are mounted on a structural steel supporting frame. There are lips on the baskets and as this screening apron moves through the water slowly and in an upward direction it carries with it particles screened from the water. After turning over the head sprockets it deposits them in a trough from which they are flushed into the river on the down stream side. The cleaning of the screen baskets is effected by having a spray pipe running back of the screen baskets which forces a continuous spray of water through the screens from the back.

In the majority of installations these screens have been placed on an incline as shown on the cut, but there are several installations which have been built in a vertical position.

#### PATTERNS BROUGHT FROM STORAGE.

EVEN when castings are wanted without alteration from a pattern which it

is certain has never been altered, it is seldom that the latter can be taken from the stores and sent into the foundry without requiring anything done to it in the pattern-shop. A pattern in regular use can be relied on, but one which has been out of use for a long time cannot. Wood is liable to shrink and warp, especially in a new pattern which has had time for this to occur, and has not received attention since being made. Shrinkage may affect important dimensions, but more frequently it causes overlapping joints which tear up sand in being drawn from the mold. The pattern must be examined for this and tested for truth on surfaces liable to warp, besides being measured and examined for breakage or possible missing details.

A warped surface may be planed true if sufficient material can be removed without reducing too much the thickness of metal or over-all measurements. Sometimes battens are screwed on to pull the surface true, and are stopped off in the mold. In other cases a concave surface can be straightened by wetting the central part and causing it to swell, and so regain its original form. A part originally circular may become elliptical through shrinkage, and this has to be rectified, often by inserting a piece.

Shrinkage in some places can be made good by putting pieces on. Sometimes the shrinkage may be in a place where it does not matter, or it may be so small in amount that it can be ignored. Damaged corners or other parts may have to be made good by letting pieces in. Fillets are often broken or missing and require replacement. Varnish wears off when a pattern has been molded from a good many times, and more varnish must be put on, preceded by thorough glass-papering and scraping where necessary to remove roughness. Work of this kind has to be done on old patterns before they go into the foundry even when the castings required are similar to previous ones.

#### FILES AND THEIR NAMES

THE Cadillac Motor Car Co., of Detroit, recently came to the conclusion that many of the men in its shops were working at low efficiency, owing to lack of knowledge concerning the names of different types of files. In many cases it was thought probable that the man knew what kind of file he wanted for his work, but in ordering it from the tool supply room, wrote the wrong name on his requisition slip. Then when the file was given him, he did not wish to admit his error and so took it out to the shop and did the best work he could with it. To overcome this difficulty, a sample board has been placed outside

the window of each tool supply room on which there is a complete set of files with the proper name under each file. With this system in use, the workman comes to the tool supply room, and looks at the board to determine the right name of the file that he wants before handing in a requisition slip. As a result, he is sure to get the proper file for his work.

#### BREAKING-IN NEW MEN

WHEN a new man begins work in an office or a department he is often left to shift for himself without an outline of his duties or an introduction to those around him. It is good to hear what a young man told me once, says a writer in *The Dodge Idea*.

"When I began here," he said, "the manager of this department talked things over with me for nearly an hour. He told me the names of all the officers of the firm, and what they did, the names of all the heads of the departments I would come in contact with, the names of the other people in the office, the name of the leading houses we did business with, and gave me a good, general idea of the work of the whole office, and special outline of my duties and possibilities. Then he took me around and introduced me to many of the people.

The result was that I quickly got my bearings, felt at home from the first, and soon settled down to hard work. In my previous position with another firm my experience was different. There were no introductions, and no outline, and no general information. My first three months were practically spent learning what the manager could have told me in an hour if he had taken the trouble to do it. The work here is twice as complicated as it was there, but I got the general plan of it well in mind the first day."

Every manager should, for the moment, put himself in the place of the new employee and realize what a confused sense he must have of a large and unfamiliar business, and how easily that confusion could be taken away by a good talk about the work in general.

**Great Lakes Record.**—Great Lakes ore carriers established a new record in the month of July, loading 9,750,157 tons, which exceeds by 242,581 tons the movement in June, which at that time was thought to have set a mark that could stand for the year. Up to August 1, ore shipments for the season aggregated 29,365,724 tons, a gain of more than 5,000,000 tons over 1913, the banner year of the trade. Detroit vessel men predict that the year's movement will approximate 59,000,000 tons.

### DELIVERY OF MUNITIONS MANUFACTURING EQUIPMENT

**I**N munitions production we have, it is generally believed, got past the stage of belated equipment shipment, in other words, machine tool manufacturers are for the most part in a position to fill expeditiously both urgent and quantity requirements. Machine tools and attachments for the production of a varied size and type shell in Canada have been largely imported from the United States, either direct by our munitions plants or through our numerous machinery agencies. Although, as indicated, shipments are again more or less normal, comparatively speaking, deliveries are little if any improved. Both munitions plants and machinery dealers find the delivery feature equally acute to that existent over a year ago, and unhesitatingly attribute it to the incapacity of our railroads with regard to freight handling. Delays of from one to two weeks are, we understand, not unusual in railroad deliveries of munitions equipment, both local and U.S. border terminals being involved.

There are, of course, two sides to this matter, and the other or railroad version while not seeking to deny the allegations of the machinery people, pleads more or less abnormal circumstances to be sufficient justification. The railroads claim that there is a shortage of freight handlers; that those meantime employed are in large percentage unaccustomed to the work, and in consequence are slow and inefficient. They also claim that the unusual amount of general freight moving is aggravating the situation.

We are sufficiently in touch with the labor situation to know that railroad help of every kind has come under the spell of the War in one direction or another, and to be more specific has responded in large numbers to either the call to the colors or to the allurements of higher remuneration offered by munitions plants. Again, railroad revenues during the past months quite bear out the contention that unusual freight traffic is passing and must needs be cared for. Canada's munitions output, maintenance and increase is however, suffering as a result of delays by our railroads in making delivery after shipment, and just so long as individual firms affect to adjust the special disabilities under which they labor, correspondingly will an all-round improvement be delayed and munitions production continue to be curtailed.

While the railroads have made the suggestion that shipments be specially marked "For Munitions," we are

of opinion that the Imperial Munitions Board, as the authoritative and governing body, should promptly call a conference of our leading machinery importers and of the railroad executives concerned to devise ways and means whereby the general irksomeness of present conditions may be minimized if not altogether eliminated. Our metal-working plants have lost none of their enthusiasm for munitions production, but find it dampened by delays in receiving equipment, especially when the latter can by a little adjustment be avoided. They were reconciled in the early days to abnormal periods between the placing of machine tool contracts and the completion and shipment of same, but now that they know that these have been eliminated, rapid transit and prompt delivery by the railroads is not unreasonably expected.

It appears to be no secret that, while Canadian manufacturers have all the shell orders they can take care of, production continues away below the expected total. Although in the returns available, the net shortage is not stated and varies considerably, in many cases both the weekly and monthly outputs are understood to be less than half what they should be. Lack of co-operation, and sections of the industry being held back through failure, of one or more supplementary sections to perform their obligations promptly are presumed to be responsible for the failure to maintain the desired output. While it has been said that many of our manufacturers have apparently trusted to luck as to their ability to fill orders which they have received, we are disposed to think that such may be reckoned as isolated instances and that what is lacking more than anything is the co-operative element.

There seems to be asserting itself the pre-war tendency to "individualism," on the part of some of our munitions plants—in other words, to keep "the other fellow" and the public as much as possible in the dark; when everything is going well, of course. While the war lasts, at any rate, let us have patriotism, and let us keep individualism buried. The delayed delivery by our railroads to our munitions plants of shell-making equipment is indicative at least of the need of co-operative effort, and no time should be lost in getting rid of the disability.

### WOMEN'S WAR WORK.

**T**HE employment of women in the manufacture of munitions in Canada has for some time now been an accomplished fact. In common with many other war developments, the probability of the ultimate adoption of such help had become a more or less familiar topic of discussion in manufacturing circles, which, combined with the wide-spread existence of such labor in Britain, had familiarized the general public with the idea.

That conditions in Britain are liberal and successful were evidenced some time ago by Sir Wm. Beardmore, who emphasized the whole-heartedness with which girls and women were working machine tools, and the stimulating effects of the knowledge their efforts were successful beyond expectation has doubtless much to do with the wonderful growth of munitions output on Britain.

In their utilization of women workers as in many other things, our enemies have betrayed a peculiar lack of common sense, not to mention consideration, and advices from a reliable authority indicate that the Central Empires are sacrificing their women on the altar of industry in a manner paralleling that of their men in battle. The number of women now employed in German engineering works is frequently as high as 80 per cent. and the question of compulsory service is being actively agitated in Germany, the claim being made that every woman should be obliged to serve her country in one way or another.

## INDUSTRIAL NOTABILITIES

**F**RANK WILTON BAILLIE, of Baillie, Wood & Croft, Financial Brokers, Toronto; president, Canadian Cartridge Co., Hamilton; president, Bankers' Bond Co., Toronto; president, Burlington Steel Co., Hamilton; vice-president, Dominion Steel Foundry Co., Hamilton, was born at Toronto, Aug. 9, 1875, the son of John and Marian Baillie.

He commenced his business career as clerk and private secretary to the late Senator Cox, Toronto; became secretary of the Central Canada Loan Co.; and, later, was general manager of the Metropolitan Bank, Toronto. He formed

FRANK WILTON BAILLIE

the firm of Baillie, Wood & Croft, 1903; organized Bankers' Bond Co., 1912; Burlington Steel Co., 1911, and Dominion Steel Foundry Co. in 1912. At the commencement of the European War in 1914, he formed the Canadian Cartridge Co. to manufacture brass cartridge cases for the British Government at Hamilton, Ont.

Mr. Baillie married Edith J. White, daughter of the late Aubrey White, Minister of Lands and Mines, Toronto; there being two sons and two daughters of the union.

His clubs are the Toronto, Albany, National, R.C.Y.C., Lambton Golf and Hamilton, and his recreations golf and motoring.

Mr. Baillie has been much in the limelight recently, through his donation of a cheque for \$750,000 to the Imperial Munitions Board, this sum constituting the profit on the manufacture of a certain quantity of brass cartridge cases, and which he obligated himself to so place.

In politics Mr. Baillie is independent, and in religion he is Anglican. His residence is 146 Crescent Road, Toronto, Ont.

Youngstown, while blue annealed sheets are still in fair demand.

**Metals**

The situation in metals, while showing little material change, is nevertheless a little more active than for some time. Copper is a little stronger owing to the absorption of second-hands. Tin is quiet and unchanged. Spelter has shown a relapse to its previous weakness, with a relative decline in prices. Lead has become quite active following a decline in Trust quotations. Antimony continues to decline.

**Copper.**—No new developments are noted in the copper situation. Odd lots of second-hand metal are gradually being absorbed, which is giving the general market a little better tone. No big business has been reported, and the producers are confining their activity to the filling of placed contracts. Reliable information as to what the producers are getting for metal is lacking, and current quotations are still nominal, based on the prices received for resale metal. The London market advanced considerably earlier in the week, but the present quotations are very little changed from that of last week; an advance of £1 on the week is shown in standard spot and £2 in electro, the latest quotations being £106 for standard spot, £103 for futures, and £125 for spot electro. New York market is quiet, with slight advance in the nominal quotations; prime lake at 26c show a ½c advance; electrolytic is 1c stronger at 27c, and castings at 24½ shows an advance of ⅛c per pound. Local dealers report a quiet market, with quotations firm and unchanged; lake, 31c; electrolytic, 31c, and 30c for castings.

**Tin.**—The arrival of fair-sized lots of tin, in addition to the quiet tone prevailing, has had a tendency to weaken the market. The present demand is light, and in view of the well-supplied market, metal is being offered at slight concessions on prices quoted. The London market is a little stronger, and advances are reported; standard spot shows an advance of £1 15s.; futures are £2 stronger; Straits spot has advanced £1 15s., and the Eastern price is up £2 10s.; the current quotations being £167 10s. £168 10s, £168 10s., and £171 respectively. The inactivity in the New York market has resulted in a decline of 2-10c per pound, the nominal price being 37 8-10c per pound. Local conditions are unchanged, and prices firm at 43c per pound.

**Spelter.**—Another reaction in the spelter situation has developed a very weak market. This is partly owing to the lack of interest shown by the brass trade. The scarcity of metal which seemed apparent a short time ago resulted in a comparatively sharp advance; but during the past few days considerable metal

## The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

**Montreal, Aug. 5.**—The general state of industrial affairs has not undergone any marked change, although the continuance of extreme weather conditions, the shortage of labor and recent happenings in munitions work have rather tended to aggravate previous conditions. Little activity is reported in the scrap market.

**Steel**

The steel situation continues strong, and prospects of possible relief in prices were somewhat destroyed by the action of the leading makers in Pittsburgh, who advanced prices \$2 a ton to 2.60c, which price has become general. Steel bands

are expected to attain a similar level, while 3c is being asked for hoops. The plate market has stiffened, and inquiry from foreign and domestic sources continues good. An advance of \$1 per ton is expected on structural shapes, which have remained at 2.50 for some months. Shell steel buying for 1917 has become a prominent feature of the market. Some makers report this product as being sold up to the end of the year, new sales being for next year's delivery. Billets and sheet bars are quoted at \$42 to \$45 Pittsburgh, wire rods being \$55 and higher. Galvanized sheet prices show a slight decrease in sympathy with the spelter market, being quoted 4.25

has become available, which has made the market very weak. Latest cables from London show a break in the market, spot having declined £12 and futures £11, leaving the quoted prices at £47 and £42 respectively. The American market has fallen off  $1\frac{1}{2}$ c per pound, and the nominal quotation for prompt metal is 8 8-10c per pound. Local dealers have declined 1c on a quiet and weakening market, the current quotation being 14c per pound.

**Lead.**—Considerable activity has developed as a result of a decline in the Trust price of lead. With the drop recently made, it is expected that consumers will renew their interest in the market, as it is generally supposed that many of them are coming to the end of their reserve supply. The decline does not indicate a weakness in the general situation, but the leading interests have done this to get hold of some of the business that has been going to independents. Heavy buying by consumers may result in a return, in some measure, to former prices. The London situation is unchanged, with the exception of a slight advance in spot metal. In an effort to stimulate buying, the Trust has declined  $\frac{1}{2}$ c on last week's price, and the outside price has declined  $\frac{1}{4}$ c, which puts both interests on the same basis of 6c per pound. Dealers here report a fair market and a decline of  $\frac{1}{4}$ c per pound; current quotations being  $8\frac{1}{4}$ c.

**Antimony.**—This metal is in very light demand and inquiries are almost nil. In many cases stocks are held by dealers that cost them over twice what they could get for it to-day. With labor conditions as they are at present, it is believed that the production of antimony at current prices must be carried on at a loss. The nominal price in New York is now  $12\frac{1}{2}$ c, and it is thought that metal could be bought even cheaper. Dealers here report a dull market on declining prices, a drop of 3c during the week putting antimony at the low figure of 16c per pound.

**Aluminum.**—Conditions are unchanged and prices are firm at 68c per pound.

**Toronto, Ont., Aug. 8.**—The continued warm weather while being decidedly beneficial to the crops is affecting the steel trade by causing a reduction in output. Incidentally the crop prospects are very favorable and as a result an optimistic feeling prevails in business circles regarding the industrial situation. While great progress has been made in the manufacture of munitions, the daily deliveries being valued at nearly \$1,000,000, production is considerably less than was hoped for or expected. Lack of co-operation is responsible for this unfortunate state of affairs, which has resulted in a shortage

of some parts thus delaying the completion of the finished shells. Orders for shells placed by the British Government in Canada now total nearly \$500,000,000 of which amount \$200,000,000 have already been delivered. It will thus be seen that there is no lack of orders and that there is enough business in sight to keep the shell plants fully occupied for many months. After a long period of quiet the Allies are again placing large contracts for munitions with manufacturers in the United States. Three things have marked the new buying movement; the size of shells, the rapidity with which orders are being closed and the extension of delivery periods until May 1917. This indicates that enormous demand for munitions and also that further large orders are assured for Canadian manufacturers if deliveries can be maintained at the desired amount.

#### CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion \$100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

#### Steel

Conditions in the steel trade continue very active although the output of the mills has been somewhat curtailed owing to the hot weather. The domestic demand is light as is usually the case at this time of the year, but export business continues heavy with no indication of falling off. The demand for munitions being as insistent as ever, the steel companies are making a big effort to supply the necessary steel, consequently the production of rails has been affected. On this account rails are being imported from the States by Canadian railways. The C.P.R. has placed at Chicago a contract for 14,000 tons against its rail enquiry for 25,000 tons. A considerable quantity of barb wire has also been imported into Canada from mills in the States. As was expected, galvanized pipe has declined due to cheaper spelter, but black pipe is unchanged. The situation in boiler plates is getting worse and prices are very firm with a possibility of an advance at no distant date. Boiler tubes are unchanged and the market quiet. Both domestic and export demand are only fairly active on bolts and nuts and prices

are unchanged. Wood screws however are in good demand and may advance.

Galvanized sheets are firmer but the situation is unchanged and the market is steady. Spelter has not declined any further and black sheets continue firm. Prices on galvanized sheets are a little firmer in the U.S. market but unchanged locally. Black sheets are in rather light demand at present, but the mills are well filled on old contracts on which they have a good accumulation of specifications, enough to run them three months or more, on an average. Blue annealed sheets are quite firm with a good tonnage demand for both nearby and far off deliveries. Prices on sheets continue to be rather irregular in the primary market but local quotations are unchanged.

In the United States the export demand for steel products is heavier and continues to sustain the market as domestic enquiry has quieted down although more activity is looked for next month. The chief feature of the market continues to be the very heavy demand for semi-finished steel in the form of billets, sheet bars and ingots while there is also a big export demand for barb wire and structural material. Steel bars are unchanged at 2.50c, plates 3.50c and shapes 2.50c Pittsburgh. Bessemer billets have advanced \$1 and are now quoted at \$43.00 per ton Pittsburgh. Open hearth billets and sheet bars, and forging billets are unchanged. The Carnegie Steel Co. has announced an advance of \$2. a ton on steel bars. The company is reported to be filled up on bars for ten months production but the other mills can hardly be considered, on the whole, as filled up so far ahead. The above advance will probably be followed by increases in other lines and it is expected a similar increase in wire prices will be announced soon.

#### Pig Iron

The hot weather is having the effect of reducing the production of pig iron but otherwise the situation is unchanged. The market continues quiet and prices are unchanged.

#### Machine Tools

The demand for machine tools for munitions plants continues to occupy the attention of dealers to the exclusion of practically everything else. There are indications that a great many more shells will be required than was anticipated, even a short time ago, and considerable activity in the machine tool market is thus assured for some time to come. The shells now required are mostly of the high explosive type and of large calibre. The tools principally required are heavy duty lathes having a swing from 24 in. to 30 in. Deliveries on such

equipment are fairly good now, but prices have an upward tendency. With regard to deliveries local dealers are complaining about shipments being held up in the freight yards, the delays ranging from one to two weeks. It is believed that some arrangement will be made to relieve the situation as it is of the greatest importance that machine tools, destined for munitions plants, should be delivered as soon as possible.

### Supplies

The demand for machine shop supplies continues brisk and prices continue very firm. The market is very steady and there are very few price changes to note. A sharp advance has been made in linseed oil which is now quoted at 90c for raw and 93c for boiled oil. Turpentine has declined 1c and is quoted at 69c one gallon. A break in the price of Pennsylvania crude oil has unsettled the market as it will probably affect the refined situation. No change however has been made in gasoline in the meantime although later on in the year prices may be easier.

### Metals

The general situation in the metal market is unchanged and prices have been maintained at last week's levels with the exception of lead which has declined. A good demand for metals for munitions continues but ordinary business is quieter on account of the usual summer dullness. Copper quotations are still nominal but conditions in the market are improving because of the gradual absorption of metal in second hands. The tin market is dull and easy, at unchanged quotations. Spelter is dull with comparatively little interest being shown by consumers. The Trust has reduced its price on lead to the same level as the independents. Antimony continues weak and quotations nominal, while Aluminum is also unchanged.

**Copper.**—The buying movement which has been so long expected in the copper market has not developed yet but prices are unchanged and nominal. Comparatively little copper has been available recently as many refiners sold nearly all their production some time ago. If consumers can hold out until the end of September without heavy buying, prices may decline, but if they are obliged to buy heavily soon, an advance in prices is expected. Quotations are unchanged at 29c per pound.

**Tin.**—The market is quiet and dull at unchanged quotations. The demand for tin is light as consumers are not taking much interest in the market for either spot or futures. Tin is quoted locally at 44c per pound.

**Spelter.**—The demand for spelter continues light particularly from the brass

mills although galvanizers are buying more metal. The market is steadier but quiet and unchanged at 13½c per pound.

**Lead.**—The Trust have reduced their price ½c per pound to the basis of 6.00c New York, bringing the price to the same level as the outside market. The independents however are cutting prices which indicates continued weakness in the market. Buyers who have been holding back in anticipation of this reduction are expected to come into the market now, but the buying movement has not started yet. Lead had declined locally and is now being quoted at 8¼c per pound.

**Antimony.**—The market continues weak with prices nominal and unchanged at 19c per pound.

**Aluminum.**—There is nothing of particular interest to note in the market and quotations are unchanged at 68c per pound.

### WORLD-WIDE BLACKLIST

SYREN AND SHIPPING, in the course of an article protesting against American criticism of the British blacklist on certain commercial houses, says the total number of blacklisted firms in all countries exceeds 1,500 as follows; Spain, 167; Brazil, 140; Netherlands, 120; Argentina and Uruguay, 95; Morocco, 88; Portuguese East and West Africa; Guinea and Rio Muni, 87; Japan, 86; United States, 85; Norway, 83; Portugal, 79; Sweden, 72; Netherlands and East Indies, 70; Ecuador, 69; Persia, 56; Greece, 50; Philippines, 44; Peru, 41; Chile, 35; Bolivia, 22; Cuba, 10; Central America, 5 Paraguay, 3; Columbia, 1.

Syren and Shipping asks: What has America to protest about? Japan does not talk of remonstrances and protests, and she is our Ally. Neither, so far, has Brazil nor other countries concerned, except Argentina."

### CANADIAN RAILROAD EARNINGS

GROSS earnings of the three big railroad systems of Canada in July were the largest for any month of the current year to date and, with the exception of last October, the largest for any month since the recovery from the 1914 slump. The aggregate of \$20,956,091 was approximately a million dollars higher than the May total, and \$1,110,000 higher than the June total. As compared with the same month a year ago there was a gain of \$7,040,445, or 50.6 per cent. For the seven months of the current calendar year the gross earnings of the three systems aggregate \$125,559,779, a gain of no less than \$36,819,066, or 41.5 per cent.

A fair indication that the volume of traffic handled by the roads in July was

quite exceptional for a midsummer month is afforded in a comparison with the returns for last October, when every available car was being pressed into service to handle the record-breaking crop in the West. In October, 1915, the total gross was \$21,656,191, or only \$700,100 greater than the July, 1916, total.

The C. P. R. gross figures for the month give a total slightly less than that of July for either 1912 or 1913, but apart from those months it was the best July in the company's history in point of volume of business, and will probably be the best in point of net profits. The C. N. R., with new branch lines linked up, makes a spectacular showing with a 95.5 per cent. gain for the month, while the Grand Trunk improved on its average monthly gain since the beginning of the year.

Gross earnings for the month compiled from the completed weekly returns with those for the last ten days of July, and the increases over a year ago follow:

Road.	July gross.	Inc.	P.C.
C. P. R. . .	\$11,795,000	\$4,348,000	58.4
G. T. R. . .	5,326,891	819,945	18.2
C. N. R. . .	3,834,200	1,872,500	95.5
Totals..	\$20,956,091	\$7,040,445	50.6

The returns for the last ten days of July follow:

Road.	Earnings.	Inc.	P.C.
C. P. R. . .	\$3,800,000	\$1,324,000	53.5
G. T. R. . .	1,810,713	273,572	17.8
C. N. R. . .	1,207,300	572,400	90.1
Totals..	\$6,818,013	\$2,169,972	46.6

Aggregate gross earnings of the three system by months so far this year, and the increases over 1915, follow:—

Month.	Earnings	Inc.	P.C.
Jan. ....	\$14,724,216	\$3,966,003	36.9
Feb. ....	14,667,915	3,237,879	28.3
March ..	17,344,243	3,731,539	27.4
April ...	18,077,805	4,959,127	37.8
May ....	19,959,336	7,224,934	56.7
June ....	19,840,173	6,659,139	50.5
July ....	20,956,091	7,040,445	50.6

**Selection of Coal.**—The proper selection of coal for each plant is essential to secure the maximum economy. Some plants will find screenings to be the most economical, while a plant in the same block may find run-of-mine to be the best. Still another plant might find nut, pea and screenings the best. Local conditions must be considered, and tests are the only way in which the best kind of coal can be determined. What your neighbor finds to be the best may be the worst for your plant. Price per ton has very little to do with this matter; it is purely a case of the cost of fuel per pound of steam.

## U.S. FIRMS AND INDIVIDUAL BLACKLIST

THE Official Gazette of the British Government has published the following names of American individuals and firms placed on the blacklist under the Trading with the Enemy Act:—

Philip Bauer Co., 68 Broad street, New York.  
Beer, Sondheimer & Co., New York.  
Simon R. Blumenthal, of Zimmerman & Forshay, New York.  
Herman Botzow, of O. C. Kanzow & Co., New York.  
Brasch & Rothenstein, 32 Broadway, New York.  
Maurice Bunge, of MacLaren & Gentles, New York.  
Alf. Burun, of Brasch & Rothenstein, New York.  
Goldschmidt Chemical Company, 60 Wall street, New York.  
Goldschmidt Detinning Company, 60 Wall street, New York.  
Goldschmidt Thermit Company, 90 West street, New York.  
Gravenhorst & Co., 96 Wall street, New York.  
Carl Grubnau & Son, 144 Arch street, Philadelphia, 74 Wall street, New York and Boston.  
Oscar L. Gutelman, of Knauth, Nachod & Kuhne, New York.  
Charles Hardy, 50 Church street, New York.  
Hasenclever & Co., 24 State street, New York.  
Bernhardt, Hasenclever & Soehne, 21 State street, New York.  
Maryan H. Hauser, of Zimmerman & Forshay, New York.  
Alfredo Hirsch, of MacLaren & Gentles, New York.  
Franz H. Hirschland, of Goldschmidt Thermit Co., New York.  
Robert W. Howe, of Brasch & Rothenstein.  
William E. Hamburg, 25 Beaver street, New York.  
International Hide & Skin Company, 59 Frankfort street, New York.  
International Import and Export Company, 136 South Fourth street, Philadelphia.  
J. Isaacs, of John Simon & Bros.  
Max Jaffe, 15 William street, New York.  
J. A. Kahl, 82 Beaver street, New York.  
Kanzon & Co., 11 Broadway, New York.  
Otto C. Kanzon, of Kanzon & Co., New York.  
H. Kempner, Cotton Exchange, Galveston, Texas.  
Knauth, Nachod & Kuhne, 15 William street, New York.  
Mary I. Knauth, of Knauth, Nachod & Kuhne, New York.  
Wilhelm Knauth, of Knauth, Nachod & Kuhne, New York.

Hermann C. Kupper, 52 Murray street and 536 111th street, New York.  
MacLaren & Gentles, 222 Produce Exchange, San Francisco.  
George W. McNear, 433 California st., San Francisco.  
A. Magenheimer, 68 Broad street, New York.  
Marx Maier, 200 Fifth avenue, New York.  
Merchants Colonial Corporation, 45 William street, New York.  
Carl Muller, of Muller, Schall & Co.  
Ernest Muller, of Schuchardt & Schutte.  
Muller, Schall & Co., 45 William street, New York.  
Frederick Muller-Schall, of Muller, Schall & Co., New York.  
Maris Nachod, 15 William street, New York.  
National Zinc Corporation, New York.  
Richard Neuhaus, of the Electro Bleaching Gas Company, New York.  
K. & E. Neumond, 25 Broad street, New York.  
Rolin C. Newton, 15 William street, New York.  
Norfolk Refining & Smelting Company, of Virginia.  
Orenstein & Kopper, of Pennsylvania.  
Edmund Pavenstedt, of Muller, Schall & Co., New York.  
Leopold Pelatz, 17 Battery Place, New York.  
Petroleum Products Company of California, San Francisco.  
Louis J. Rees, of Zimmerman & Forshay, New York.  
Reuter, Broeckelman & Co., 59 Pearl street, New York.  
Alfred Richter, of Reuter, Broeckelman & Co., New York.  
Roessler and Hasslacher Chemical Company, 100 William street, New York.  
Rubber and Guayule Agency, 108 Water street, New York.  
Townsend Rushmore, 82 Beaver street, New York.  
William Schall, Jr., of Muller, Schall & Co., New York.  
Schenker & Co., 17 Battery Place, New York.  
G. F. Schloetelborg, 318 Globe Building, Seattle.  
Paul Schmidt, of Rubber and Guayule Agency, New York.  
Schenker & Co., 17 Battery Place, New York.  
Schuttle, Bunemann & Co., 15 William street, New York.  
John S. Scully, of Zimmerman & Forshay, New York.  
Siemssen Company, 82 Beaver street, New York.  
John Simon & Bros., 15 William street, New York.  
L. Sonneborn Sons, 262 Pearl street, New York.

Southern Products Trading Company, 15 William street, New York.  
Edward Stegemann, Jr., of Brasch & Rothenstein, New York.  
Superior Export Company, 90 West street, New York.  
Texas Export and Import Company, Galveston.  
Ernest Ulrich, 15 William street, New York.  
Edward Weber, of Rubber and Guayule Agency, New York.  
Otto Wehrenberg, of Philip Bauer & Co., New York.  
Arend H. Weingardt, 15 William street, New York.  
Zimmerman & Forshay, 9 Wall street, New York.  
Carlowitz & Co., 82 Beaver street, New York.  
Charles Cullen, Ocala, Florida.  
Armin Czech, of International Import and Export Company.  
Eugene Dittzen Co., 166 West Monroe street, Chicago, and 218 East 23rd street, New York.  
Electro Bleaching Gas Company, Buffalo avenue, and Union street, Niagara Falls, and 25 Madison Square avenue, New York.  
E. H. Erlanger, 60 Wall street.  
Carlos Falk, of MacLaren & Gentles.

## GUN ABOARD DOES NOT AFFECT STATUS.

THE fact that a merchant ship is armed with a gun with which to defend itself does not change its character so as to permit men engaged as crew to refuse to go on board and serve, even though the contract they have signed are the ordinary pre-war Articles relating to merchant ships.

This was the effect of a judgment handed down recently by Judge Leet in the case of five firemen who refused to board a ship sailing from Montreal to England. The men were sentenced to ten days each in jail, His Honor remarking that he wished to be lenient under the circumstances, and that he believed that the men had probably acted in good faith. The men were engaged in New York through agents of the steamship company, it having been found impossible to get the necessary complement here. This is the first case of this kind which has been tried in Canada, and the judgment establishes, therefore an important precedent.

### Judge's Summing Up.

His Honor remarked at the outset that the charge of desertion against the men could not stand, for it had been shown that they were under surveillance from the time of their arrival here. The other charge was of refusing to go on board the ship. The judge re-

viewed the facts of the case, the hiring of the men in the United States, their arrival here, the non-arrival of their baggage, and its subsequent appearance as a result of efforts on the part of the shipping company.

"The only question was to decide whether the fact that the ship was armed makes any difference," he continued. "I have no experience in marine matters, and do not know much about the law regarding the arming of a merchant ship for defensive purposes. It is a question whether the carrying of this gun would change the nature of the boat, or make such a difference in the condition of affairs as would allow the men to refuse to carry out their contract. Certain facts connected with the case are matters of common knowledge. These men knew, must have known, that there was war between Great Britain and Germany, and that every vessel leaving a Canadian port was in danger, that it might be overhauled by a German cruiser or submarine, captured or sunk. That is a fact that is so public that everybody must know of it. If they were willing to come and take service on

a merchant ship, then the fact that it was sailing from a Canadian port would make no difference.

"From the evidence given, and the authorities cited," continued His Honor, "I do not think that it does make any difference that the ship carried this gun." He remarked on the means of protection which would be afforded the ship across to England.

"I, therefore, come to the conclusion that because it carried one gun for the purpose of defence is not a reason for declining to go on board. They knew, when engaged in New York, that Canada was a British country, and that the ship was going to England and return. All the risks of the trip were appreciated, and I cannot see that the fact that the ship carried a gun made any difference in the agreement, or added to the risk, or allows a pretension to claim that the engagement was made under false pretences. I have, therefore, to find that you are guilty."

In regard to the penalty, the court pointed out that the ship had sailed short five of its crew because of the action of the accused, and the result

would perhaps be serious to the ship, and in any case mean more work for those on board. However he felt that the men had acted in good faith, and their side of the case had been put by their spokesman in a sincere manner, and under the circumstances he would not be severe. Sentence of 10 days followed.

### SAFETY WORK POSSIBILITIES

SAFETY work enables not only the employee to get a clearer and better understanding of what the management is trying to do, thereby creating a kindlier feeling on the part of the employee toward the employer, but it also enables the employer to get a closer insight, perhaps a more sympathetic understanding of the worker's attitude. After all, the distance between the top of the heap and the bottom, does not change human nature very much. Both top and bottom are usually cast in pretty much the same mold. Boss and bossed—God made them both.

## CANADIAN COMMERCIAL INTELLIGENCE SERVICE

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

### CANADIAN TRADE COMMISSIONERS.

**ARGENTINE REPUBLIC**  
H. R. Poussette, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

**AUSTRALASIA**  
D. H. Ross, Stock Exchange Building, Melbourne. Cable address, Canadian.

**BRITISH WEST INDIES**  
E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

**CHINA**  
J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

**CUBA**  
Acting Trade Commissioner, Lonja del Comercio, Apartado 1290, Havana. Cable address, Cantracom.

**FRANCE**  
Philippe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

**JAPAN**  
G. B. Johnson, P. O. Box 109, Yokohama. Cable address, Canadian.

**HOLLAND**  
Acting Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address, Watermill.

**RUSSIA**  
L. D. Wilgress, Omsk, Siberia.  
C. F. Just, Canadian Government Commercial Agent, Alexandrinskaya Ploshad 9, Petrograd.

**NEWFOUNDLAND**  
W. B. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

**NEW ZEALAND**  
W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

**SOUTH AFRICA**  
W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

**UNITED KINGDOM**  
N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian.

J. E. Ray, Central House, Birmingham. Cable address, Canadian.

J. Forsyth Smith, Fruit Trade Commissioner, 27-28 Pearl Building, East Parade, Leeds. Cable address, Canadian.

F. A. C. Bickerdike, Canada Chambers, 36 Spring Gardens, Manchester. Cable address, Cantracom.

J. T. Lithgow, 87 Union Street, Glasgow, Scotland. Cable address, Contracom.

Harrison Watson, 73 Basinghall Street, London, E.C., England. Cable address, Sleighing, London.

### SPECIAL TRADE COMMISSIONER—LUMBER

H. R. McMillan, visiting Europe, Africa, Australasia and the Orient.

### CANADIAN COMMERCIAL AGENTS

**BRITISH WEST INDIES**  
Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian.  
R. H. Curry, Nassau, Bahamas.

**NORWAY AND SWEDEN**  
C. E. Sontum, Grubbegd No. 4, Christiania, Norway. Cable address, Sontums.

### CANADIAN HIGH COMMISSIONER'S OFFICE

**UNITED KINGDOM**  
W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

# INDUSTRIAL <sup>A</sup><sub>D</sub> CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

## Engineering

**Thorold, Ont.**—The Ontario Power Co. will build an addition to its machine room here.

**Shipsaw, Que.**—Price Bros. & Co., will install a 5,000 h. p. turbine and generator at their plant here.

**Sherbrooke, Que.**—H. G. James proposes making an addition to his machine shop to cost \$7,000.

**St. Catharines, Ont.**—The McKinnon Dash & Hardware Co., will build an extension to their power plant.

**Thorold, Ont.**—The Toronto-Niagara Power Co., is building a transformer house at a cost of \$100,000.

**Nelson, B.C.**—The West Kootenay Power & Light Co., is installing an 8,660 h.p. unit in their No. 2 plant.

**Osaquan, Ont.**—The Indian Lake Lumber Co., will develop a water power here. F. F. Wilson is superintendent.

**Bothwell, Ont.**—Crotty & Elliott, are having plans prepared for an oil power plant to be erected at a cost of \$5,000.

**Pembroke, Ont.**—The Pembroke Electric Light Co., will build a brick and reinforced concrete sub-station at a cost of \$303,000.

**Porcupine, Ont.**—The Northern Power Co., will install a 4000-h.p. water turbine and generator in its power plant at Wawaitin, Ont.

**Orillia, Ont.**—The E. Long Co. has taken over the Tudhope-Anderson Co.'s wheel works building and will equip it for a machine shop.

**Walkerville, Ont.**—The Motor products Corporation in which W. C. Rand of the Rand Mfg. Co. of Detroit is interested, will build a plant here.

**Thorold, Ont.**—The Ontario Paper Co., will erect a sulphite mill adjoining their plant here. W. T. Trimble care of the company has charge of the work.

**Fredericton, N. B.**—The C. P. R. will erect four concrete buildings at McAdam Junction to be used as a power house, coaling plant, storage building, and blacksmith shop.

**Ottawa, Ont.**—J. Sutherland of this city has received the contract for the erection of a power plant on Slater Street for the Imperial Realty Co., Ottawa, to cost \$30,000.

**Montreal, Que.**—William Hood & Son, are in the market for a 10 or 15-h.p. electric motor, a heavy Bliss trimming on punching press, a power hacksaw, and a 1000 to 2000-lb. drop forging hammer.

**Renfrew, Ont.**—M. J. O'Brien will proceed with his development scheme at Calabogie, where 5,000 h.p. can be had. A power plant will be erected there and a transmission line installed between that point and Renfrew.

**Port Colborne, Ont.**—The International Nickel Co. has secured an option on a site here for a nickel refinery. No definite decision has been arrived at regarding the location of the plant, but it is probable that this town will be selected.

**Sudbury, Ont.**—The British-American Nickel Co. will commence operations at once on the construction of its refinery near here. The concern is controlled by Canadians, but financed in the Old Country. It will sell its product for the present entirely to the British Government. It is supposed to be controlled by the Mackenzie & Mann interests.

**The Nova Scotia Steel & Coal Co., New Glasgow, N.S.**, contemplates making considerable extensions at its iron mines, Wabana, Newfoundland. These extensions include new hoisting equipment, boilers, pumps, compressed air plant, power lines, cables, ventilating plant, industrial railroad track, hauling cable, etc. R. E. Chambers, is manager of ore mines and quarries.

**Dartmouth, N.S.**—Involving an expenditure of \$2,000,000, work is now going forward on the Imperial Oil Co.'s new refinery on the Dartmouth shore of Halifax harbor. Over 400 acres of land have been purchased, and the plant, as originally planned, will cover 40 or 50 acres, the remainder of land being for expansion purposes. There will be storage tanks, machine shops, warehouses, and all the other equipment that goes with a modern oil refining plant. S. S. Shatford is manager.

## General Industrial

**The Noble Mfg. Co., St. Thomas, Ont.**, has been purchased by Peter Klob, of Toronto, for \$45,000.

**Penetang, Ont.**—Fire destroyed the Furnace Co.'s brick plant and machine shop. The loss which is heavy is partly covered by insurance.

**Doon, Ont.**—The plant of the Doon Fibre Co., owned by James Huber recently totally destroyed by fire, will be rebuilt and new equipment installed.

**Brantford, Ont.**—The Brantford Carriage Co. has purchased the business and plant of the Baynes Carriage Co., Hamilton, Ont. The latter concern will be closed up.

**Toronto, Ont.**—A well known chewing gum manufacturing firm, contemplate erecting a big factory in the east end at a cost of \$165,000. A building permit has been applied for.

**Chatham, Ont.**—Work has now been commenced on the \$45,000 addition to the American Pad & Textile Co., plant on Queen and Richmond street. Wells & Gray, Toronto, are the contractors.

**Winnipeg, Man.**—The Dyson Co., manufacturers of pickles, etc., are looking for a new site on which to erect a factory. This is necessary on account of the heavy demand during the past year.

**Winnipeg, Man.**—The mill and boiler-house of the Winnipeg Paint & Glass Co. factory, corner of Gertrude and Scott streets, Fort Rouge, are a total loss as the result of a fire which broke out on August 2. The loss is estimated at \$100,000, fully covered by insurance.

**Toronto, Ont.**—A. S. White, of White & Co., brokers, New York, and president of the Federal Dyestuff & Chemical Corporation, spent a day recently in the city with R. R. Boggard, in consultation regarding the plans for establishing a branch of the Federal Company in Canada. The parent corporation operates at Kingsport, Tennessee.

**Collingwood, Ont.**—The buildings and plant of the Collingwood Packing Co. was totally destroyed by fire on Sunday night. The plant has not been in operation since the company became insolvent about three years ago. The building and plant was valued at about \$150,000. Amount of insurance is not known.

## Municipal

**Hamilton, Ont.**—A steam-driven turbine pump will probably be installed at the Beach pumping station at a cost of \$100,000.

**Petrolia, Ont.**—A by-law to grant concessions and a site of 25 acres to the Lambton Flax Co., was carried on July 31 by a large majority.

**Hamilton, Ont.**—The City Council, is having plans prepared for an addition to the waterworks pumping plant to cost \$70,000. James Bain is the engineer.

**Port Moody, B. C.**—City Engineer Kilmer has arranged for the purchase of 11,000 feet of fire hose for fire protection in view of the recent installation of water service.

**Renfrew, Ont.**—The Town Council have decided to proceed with the development of power at the first chute of the Bonnechere River, where 1,500 h.p. is available. The cost of the development is estimated at \$140,000.

## Tenders

**Drummondville, Que.**—Tenders will be received August 15 for the construction of mechanical gravity filters, with a capacity of 500,000 U.S. gallons per day, also supplementary tenders for plant without machinery. W. A. Moisan, town clerk.

**Toronto, Ont.**—Tenders will be received by the Chairman, Board of Control, up to August 15, for the supply and delivery of one 5-ton travelling beam. Specifications and forms of tender may

be obtained at the Works Department, Room 12, City Hall.

**Carberry, Man.**—Tenders will be received up to August 25, for the purchase of the following oil tanks and outfits: Two complete steel oil tanks, capacity 12,000 American gallons each with two pumps, piping, fittings and all connections. Apply W. D. Card.

**New Toronto, Ont.**—Tenders will be received by the Village Council until August 14, for the construction of sanitary sewers and a sewage pumping station. Forms of Tender may be obtained and plans and specifications seen at the office of the Engineer, T. Lowes, Mimico, Ont.

**The Pas, Man.**—Tenders will be received up to August 16 for all trades in connection with the erection of a public building at The Pas. Plans and specifications may be seen at the office of the architect, G. Nelson Taylor, The Pas, Man., or at the Winnipeg Builders Exchange, Winnipeg.

**Winnipeg, Man.**—Tenders, addressed to the Chairman, Board of Control, will be received up to August 14 for the supply and delivery of 4,500 Imperial gallons of transformer oil to the City Light and Power Terminal Station. Instructions to bidders, specification and form of tender may be obtained at the office of the City Light and Power Department, 54 King Street.

**Winnipeg, Man.**—Tenders will be received until August 21 for the various works required in the completion of the New Parliament Buildings, and not included in the general contract. The works include structural steel, heating and ventilation, electrical conduit and

wiring. Particulars may be obtained from S. C. Oxfon, Deputy Minister of Public Works, Winnipeg.

**Ottawa, Ont.**—Tenders will be received until Friday, August 18, 1916, for the supply of filing cabinets for Dominion public buildings generally. Plans, specifications and forms of contract can be seen and forms of tender obtained on application to the office of Edwin Francis, caretaker, Post Office, London, Ont.; R. L. Deschamps, overseer of Dominion Buildings, Post Office, Montreal; Thos. A. Hastings, clerk of works, Postal Station "F," Toronto, and at the Department of Public Works, Ottawa.

**Ottawa, Ont.**—Sealed tenders, addressed to the undersigned and endorsed "Tender for Burleigh," will be received up to noon on 14th August, for the purchase, as she lies, of the schooner Burleigh, length 101 feet, breadth 25 ft. 6 in., depth 10 ft. 8 in., gross tonnage 148.81, registered tons 129.88, built in Shelburne, N.S., in 1904. The Burleigh is a three-masted schooner and is equipped with a 40 h.p. auxiliary gasoline engine, built by the Sterling Engine Co. Permission to examine the vessel may be obtained on application to the Captain Superintendent, H.M.C. Dockyard, Halifax, N.S., from whom further particulars may be obtained. G. J. Desbarats, Deputy Minister of the Naval Service, Department of the Naval Service, Ottawa, July 22, 1916.

**Assiniboia, Sask.**—Tenders will be received up to August 15 for the supply and delivery of the following machinery and materials:—(A)—For the supply, delivery and erection of an 150 h.p. internal combustion engine; (B)—For the supply and delivery and erection of generator, exciter, switch board, and other

## Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

**BRAZIL**  
Bahia, British Consul.  
Rio de Janeiro, British Consul General.  
**CHILE**  
Valparaiso, British Consul General.  
**COLOMBIA**  
Bogota, British Consul General.  
**ECUADOR**  
Quito, British Consul General.  
**EGYPT**  
Alexandria, British Consul General.  
**FRANCE**  
Havre, British Consul General.  
Marseilles, British Consul General.  
**INDIA**  
Calcutta, Director General of Commercial Intelligence.

**ITALY**  
Genoa, British Consul General.  
Milan, British Consul.  
**MEXICO**  
Mexico, British Consul General.  
**NETHERLANDS**  
Amsterdam, British Consul.  
**PANAMA**  
Colon, British Consul.  
Panama, British Vice-Consul.  
**PERU**  
Lima, British Vice-Consul.  
**PORTUGAL**  
Lisbon, British Consul.

**RUSSIA**  
Moscow, British Consul General.  
Petrograd, British Consul.  
Vladivostok, British Consul.  
Odessa, British Consul General.  
**SPAIN**  
Barcelona, British Consul General.  
Madrid, British Consul.  
**SWEDEN**  
Stockholm, British Consul.  
**SWITZERLAND**  
Geneva, British Consul.  
**URUGUAY**  
Monte Video, British Vice-Consul.  
**VENEZUELA**  
Caracas, British Vice-Consul.

# BRIDGEFORD 9.2" BORING LATHE

Massive strength. Superior workmanship. These features are so prominent that a mere glance at the illustration will reveal them to you. It is a machine of the heavy duty, low swing type, having a specially designed carriage with auxilliary for internal profile. Carries a 6" steel bar with male taper, allowing for light design of cutter heads; 3 automobile style speed changes, all hardened and running in oil bath. A chip tray is attached and used in conjunction with stationary lubricant tank. Regular equipment comprises everything except chuck, steady rest and cutter.

## Don't Depend on Somebody Else

For Your Small Threaded Parts

## THREAD THEM YOURSELF

**A GEOMETRIC THREADING MACHINE  
SOON PAYS FOR ITSELF**

Takes floor space 2 ft. x 3 ft. and is complete with countershaft, change speed gear, adjustable stop for gauging length of thread.

No rough threads with the Geometric. They are as true and clean as can be produced on any Screw Machine.

From 1/8-inch pipe thread to 1-inch diameter is the usual range of the machine, but where fine pitch threads are to be cut on larger diameters, it can be fitted with a Die Head that will take care of the work.

*Submit Your Threading Proposition to Us.*

apparatus; (C)—For the supply, delivery and erection of pumps, motors, piping and air compressor; (D)—For the supply and delivery of two pneumatic storage tanks; (E)—For the supply and delivery of one oil storage tank; (F)—For the supply and delivery of poles, wire and line material; (G)—For the supply and delivery of approximately 17,500 feet of 4 in., 6 in. and 8 in. steel pipe, or cast-iron pipe, and specialties; (H)—For the supply and delivery of 20 hydrants, 29 gate valves and boxes; (J)—For the erection of power station; (K)—For the supply, delivery and installation of heating plant. Complete sets of plants and specifications may be seen at the office of the consulting engineers, Murphy & Underwood, Saskatoon, Assiniboia, Sask.

## Personal

**Samuel Grover Veary**, late chief mechanical engineer Montreal Waterworks, died in Montreal on August 2, aged 75.

**C. H. Speer** has been appointed chief engineer of the Algoma Steel Corporation, in succession to J. D. Jones, who has resigned.

**G. M. Smith**, formerly of Lytle, Smith & Co., Montreal, has recently taken over the managership of the Precision Tool Co., 1665 St. James Street.

**Captain Hiram Rowe**, a retired mariner of the Great Lakes, passed away at his residence in Collingwood, Ont., on August 5, aged 72 years.

**A. E. Griffin**, of Wingham, Ont., is going to Russia in the interests of the Forley, Walsh & Stewart Railway Construction Co., of Vancouver, and expects to secure a contract for his company in that country.

**J. A. Kilpatrick**, president and manager of the Dominion Wheel & Foundry Co., of Toronto, and formerly of St. Thomas, has been appointed by the Imperial Munitions Board at Ottawa to take charge of the production of forgings.

**Thomas J. Drummond**, a prominent business man of Montreal, and a member of the Drummond, McCall Co., died at his summer residence at Castine, Me., on August 6. Mr. Drummond was born at Tawley, County Leitrim, Ireland, on September 26, 1860.

**C. Stendol** has been appointed manager of the steel department of the Canada Cement Co., Montreal, in succession to C. H. McMillan, who has resigned. Mr. Stendol was formerly with the Dominion Steel Corporation, and previously held an important managerial position with the Algoma Steel Co., Sault Ste. Marie, Ont.

**Captain F. Ross Newman** has been invalided to England, suffering from trench fever. He has been at the front for some fifteen months, having gone there with a Toronto battalion which formed a unit of the 2nd Canadian Overseas Contingent. Previous to enlistment, Captain Newman was sales manager at Toronto for the Canadian Fairbanks-Morse Co.

**John D. McEachren**, a former well known manufacturer of Galt, Ont., died recently at Indianapolis, Ind. The late John D. McEachren was in his 81st year and was born in St. Croix, Quebec. He came to Galt from Harriston and after being engaged in various pursuits for several years, founded the McEachren Heating and Ventilating Co., now Sheldons, one of the largest plants manufacturing heating and ventilating machinery in Canada.

**Brig.-Gen. Sir Alexander Bertram**, deputy chairman of the Imperial Munitions Board, will visit the West during the next few weeks in connection with the output of munitions, and particularly the production of certain raw materials, such as copper. He will visit copper mines in British Columbia with a view to expediting shipments. After returning from the West, General Bertram will in all likelihood accept an invitation to cross the ocean and visit the battle front.

## Contracts Awarded

**Quebec, Que.**—The City Council have awarded a contract for batteries for the fire alarm telegraph system to Goulet & Belanger at \$3,041.

**The Boving Hydraulic & Engineering Co.**, Lindsay, Ont., have been awarded a contract for water turbines by the City of Sherbrooke, Que.

**Quebec, Que.**—Goulet & Belanger, of this city, have been awarded the contract for the Quebec Exhibition lighting system. Estimated cost, \$11,000.

**Hamilton, Ont.**—The United Gas & Fuel Co. have awarded a contract for the equipment of their new plant here to the Gas Machinery Co., Cleveland, Ohio.

**Iroquois, Ont.**—The Village Council have awarded a contract to the Swedish General Electric Co., Toronto, for a 125 kw. generator with exciter and switchboard.

**Toronto, Ont.**—Witchall & Son, Toronto, has received the contract for the erection of an ice plant for the William Davies Co., Front Street East, to cost \$50,000.

**Edmonton, Alta.**—Nesbitt & Co., Edmonton, have been awarded the con-

tract for the erection of a machine shop at Edmonton for the C. N. R. at a cost of \$19,500.

**Chatham, Ont.**—Wells & Gray, Toronto, have been awarded the contracts for the addition to the American Pad & Textile Co. factory here.

**Prince Rupert, B.C.**—The City Council have awarded a contract for pumping equipment to the Canadian Fairbanks-Morse Co., and for steel pipe to Campbell Gordon & Co., Vancouver, B.C.

**New Toronto, Ont.**—The general contract for the erection of a factory for the Goodyear Tire and Rubber Co., has been let to the Dominion Construction Co., Toronto. Approximate cost, \$750,000.

**Niagara Falls, Ont.**—The Town Council has awarded the contract to the Electro Bleaching Gas Co. of New York, for the installation of a liquid chlorine to cost \$900. The plant of this company is in Niagara Falls, N. Y.

**Port Arthur, Ont.**—The Thunder Bay Contracting Co. of Port Arthur was recently awarded the contract for the basement and cement work on the new Canadian Government railway elevator to be erected at Transcona, Man.

**Ottawa, Ont.**—The contract for the construction of the new Customs house and examining warehouse at Toronto has been awarded to the Fuller Construction Co. The buildings will cost about \$1,500,000, and are to be started at once.

**Arnprior, Ont.**—The Galetta Electric Power & Milling Co. have awarded a contract for a turbine to the Boving Hydraulic & Engineering Co., Lindsay, Ont. A 400 kw. generator and additional switchboard equipment will be supplied by the Canadian Westinghouse Co., Hamilton, Ont.

**Victoria, B.C.**—The contract for the 450 or 500 tons of steel to be used in the construction of the three ships being built in the local shipyards of the Cameron-Genoa Mills Shipbuilders, has been secured by the Victoria firm of Messrs. F. G. Prior & Co. The steel which will be required under the contract will consist of bars, bolts, rings, rivets, etc., and the whole order for the three ships will be delivered on the ground within six weeks' time.

## Trade Gossip

**Laurie & Lamb**, Montreal, have received an order for a 500 h.p. Belliss & Morecom engine for the Belgo-Canadian Pulp & Paper Co., Shawinigan Falls, Que.

## Our Competitor's Argument

One of our competitors—one for whom we have much respect—one who manufactures both high-speed and carbon drills—in some recent advertising shows conclusively that it is profitable to use high-speed rather than carbon drills, *even at ten times the cost.*

### Our Competitor's Figures

High-speed drills cost ten times carbon drills, with present high prices of steel.

High-speed drills will do five times the work of carbon drills—a very conservative comparison.

But assume they will do only four times the work—ultra conservatism—

### Cost of Drilling 10,000 Holes

#### WITH CARBON DRILLS

20 Carbon Drills @ \$1.00 .....	\$ 20.00
20 Men @ \$2.50 per day .....	50.00
100% *Machine Expense .....	50.00

Total Cost .....\$120.00

#### WITH HIGH-SPEED DRILLS

5 H. S. Drills @ \$10.00 .....	\$ 50.00
5 Men @ \$2.50 per day .....	12.50
100% *Machine Expense .....	12.50

Total Cost .....\$ 75.00

\*Machine expense includes taxes, insurance, depreciation, repairs, power, etc.

### Our Competitor's Conclusion

"When you are using drills of  $\frac{3}{8}$ " or over, if your equipment is favorable, we sincerely recommend the high-speed drill."

### Our Conclusion

We heartily endorse our competitor's conclusion—and we sincerely hope he will not take offense at our use of his argument.

This sounds like humor—but it is not—it is fact.

We Manufacture High Speed Drills

## CELFOR TOOL COMPANY

BUCHANAN, MICHIGAN

## I BELIEVE

In Safety First and always.  
In providing for the Health of my Fellow Workmen.  
In Light and Air and sanitary Working Conditions.  
In clean, fresh drinking water for everybody.  
In the Safety, Economy and Man-betterment.

## PURO SANITARY DRINKING FOUNTAIN

(MADE IN CANADA)

The loss of a man through impure drinking water is a crime that "the front office" must bear.

An ugly statement, isn't it? But true, absolutely.

When a man comes to work in your factory he puts his health in your keeping.

Are you willing to take chances on such a trust?

Impure drinking conditions are responsible for more tragedies than any machine ever built.

Apply the "Safety First" Principles to your water supply; don't deny your men a clean, fresh drink of water.

Conserve their health and they will improve your profits; make yourself as worthy of the name of "employer."

Install the Gold Medal winner Puro in your plant, office and shop alike.

The only Sanitary Drinking Fountain that is safe, sanitary, simple, automatic in control and easily attached.

Let us tell you just what it will cost you to

## Stampings and Metal Specialties

We have the plant and equipment for turning out stampings of the highest quality in brass, copper, aluminum, tin and steel, and are prepared to undertake the manufacture of metal specialties of any description.

PUNCHES, DIES, TOOLS.

COLEMAN FARE BOX COMPANY, LTD.

20 Bond St., Toronto

Galt, Ont.—The annual excursion of the Mutual Benefit Society of the Canada Machinery Corporation Works to Burlington Beach on July 29 was a decided success.

The Canadian General Electric Co., Toronto, have been awarded a contract for a 5,000 k.v.a. turbine and generator, condenser and pumps, etc., by the Acadia Coal Co., Stellarton, N.S.

The Canadian Westinghouse Co., of Hamilton, Ont., have been awarded a contract by the Great Lakes Power Co., of Sault Ste. Marie, Ont., for the electrical equipment for their new power plant.

The International Time Recording Co. has been incorporated at Ottawa, with a capital stock of \$500,000, to manufacture time clocks, etc., at Toronto. Incorporators: E. B. Ryckman, A. L. Reid and S. G. Wharin, all of Toronto.

Ottawa, Ont.—The corner-stone of the new Parliament Buildings will be laid by his Royal Highness the Duke of Connaught on September 1 next. This date was fixed by the Parliamentary Reconstruction Committee owing to the fact that it was on September 1, 1860, that the corner-stone of the old building was laid by the late King Edward.

The Smithsonian Institution, Washington, D. C., announces that it has made an appropriation to further experiments in the dissipation of fog by electricity and that the investigations will be carried out under the general direction of Dr. F. G. Cottrell, who has already done much toward the practical precipitation of dust, smoke and chemical fumes in large industrial establishments.

Saguenay Railway Taken Over.—The agreement between the Government and the owners of the Quebec & Saguenay, Quebec, Montmorency & Charlevoix, and Lotbiniere & Megantic Railways for the taking over of the three roads was finally signed up at a meeting of the Cabinet Council on August 2. The agreement is along the lines of the legislation passed last session. The total amount to be paid over amounts to about \$7,000,000. The Government will proceed as soon as possible with the completion of the Quebec and Saguenay road.

Canadian Munitions Plant for Women.—The Gooderham & Worts Distillery at Toronto is being turned into a munitions plant for women operators, through the generosity and patriotism of Col. A. E. Gooderham. In the reconstruction and equipment arrangements every possible comfort has been provided for the women employees. The latter will operate on three shifts of eight hours each. Motors will call to

## KEYSEATER

for Milling Internal Keyseats

This tool is an attachment for the drilling machine, and is regularly made with straight shank for gripping in the drill chuck; taper shank can be had if desired. The tool is fitted with a high-speed steel rotary cutter for milling internal keyseats in one cut. To complete a keyseat it is only required to pass the tool through the hole just once. Innumerable inexpensive eccentric bushings are supplied whereby the tool may be bushed to meet any diameter above its own. Write for Catalog C for full detail.

take them to their employment, while gas ranges will stand ready to produce cups of tea and other sustenance; in short, nothing will be left undone to make the work as easy and as congenial as possible. The matron appointed has been given carte blanche to carry out such ideas as occur to her along this line.

## Building Notes

**Barrie, Ont.**—The Bell Telephone Co. will erect a new exchange building here. Contracts will be awarded shortly.

**Toronto, Ont.**—Mouney & Co. have been granted a permit for an addition to their premises at 334 Parliament Street to cost \$4,000.

**Toronto, Ont.**—The Harry Webb Co. has received a permit for the erection of a bakery to cost \$78,000, at the corner of Kendal Avenue and Davenport Road.

**Toronto, Ont.**—The city architect has approved the plans and issued a permit for the erection of a twelve-storey factory building by the T. Eaton Co., on Alice Street, to cost \$625,000. The building will be of reinforced concrete fireproof construction.

**Toronto, Ont.**—A new moving picture theatre will be built at 141 and 143 Yonge street by L. J. Applegath & Sons for His Majesty's Theatre Co., and will cost \$100,000. Plans are being prepared by F. W. Lamb, a New York architect. It will be absolutely fireproof and will have a seating capacity of 1000.

**Toronto, Ont.**—The Toronto Hydro-Electric Commission are having plans prepared for the erection of a large stores building at the corner of Murray Street and Caer Howell, to cost between \$200,000 and \$250,000. When the need arises the building will be enlarged, and it is expected that when complete it will be worth \$400,000.

**Halifax, N. S.**—The French Cable Co., of Paris, has awarded to the Standard Construction Co., of Halifax, the contract for construction of one of the finest cable buildings in America, to be erected on the North Dartmouth shore. The contract calls for construction of wharf and building, involving an expenditure of \$70,000. The building will be three stories in height, and 360 feet by 140 feet.

## Wood-Working

**Fesserton, Ont.**—The stave and saw mills of the Fesserton Timber Co. here were totally destroyed by a fire on Saturday night.

# Mechanical Applications of Oxy-Acetylene Welding Apparatus

## Staff Article

*In few fields of industrial effort have the applications of scientific research had so much influence on the welfare of mankind as in the utilization of high temperatures. Methods of obtaining, controlling and applying intense heat are in a state of constant evolution, and in variety of applications, economies effected, and future possibilities as a heat generator oxy-acetylene gas already occupies an important position in the industrial world.*

**F**EW industrial processes have undergone such rapid and extensive development, or become so indissolubly linked to existing industries by virtue of their merits as the use of oxy-acetylene gas in connection with iron, steel, and metal manufacture. In the short space of ten years the applications of this process have increased enormously, and with the development of new apparatus and the improvement of methods as indicated by experience, the results to be obtained in many lines of manufacture are such that a forced return to pre-oxy-acetylene days would be little short of an industrial calamity.

The rapidity with which scientific inventions are adapted to the requirements of industry is well indicated by the work of the Davis-Bournonville Co., which in 1906 began to develop the patent rights for the independent positive-pressure type of welding torch, the basic principles of which have been amply justified during the past decade. During the early years of development much of the work was confined to repair and reclamation, but although originally more or less of a salvage process, the application of oxy-acetylene welding and cutting to straight manufacturing operations soon began to receive attention until as the result of

proven merit, it occupies a recognized place in the equipment of certain industries.

Five distinct types of machines have been evolved by the firm referred to, special apparatus to meet particular re-

quirements on the tracing end of which is mounted a tracing roller propelled by a small electric motor. Mounted on the frame is a special cutting torch, which can thus be moved over the surface of the work as desired and any shape, regular

FIG. 2. CRANKSHAFT BLANKS CUT FROM THE COLD SLAB BY THE OXYGRAPH APPARATUS.

quirements being produced when necessary. The machines include the Oxygraph illustrated in Fig. 1. This apparatus consists of a pantograph frame

or irregular can be cut out of the metal, the cut being started and stopped at any desired point without cutting through the side of the work. The frame cuts very rapidly, an average travel of 12 in. per min., being easily maintained. As shown in the illustration, the self propelled tracing wheel is guided along the outline of any desired shape so that exact duplicates can be produced at any time the amount of reduction between the drawing and the work being one-half.

That such a machine has valuable manufacturing applications can be seen from Fig. 2, where crank shafts in the rough are cut from the solid rolled slab. Such cutting, however, is not confined to moderate weights of metal as a cutting torch of the type shown has been successfully used in trimming slabs of armor plate to shape, cutting a slice 1 in. thick or more from the end of a block 16 in. deep, at the rate of 1 sq. in. of section cut per minute.

Kindred mechanical devices include the Holograph for cutting holes in the web of rails or in structural iron; the Radiograph for the purpose of cutting plates or sheets into round oval or irregular forms; the Railagraph, for cut-

FIG. 1. CUTTING OUT BLANKING DIES WITH THE OXYGRAPH APPARATUS.

ting the rails of steam or electric railways, or all kinds of forms in structural work.

Automatic welding machines have likewise been developed, such as tube welding machines for the welding of commercial steel tube and barrel welding

of a column, so placed that one arm of the frame passes inside the barrel body while the other one is on the outside, the flames from the two torches rapidly bringing the metal to a welding temperature. Variable power feed is provided for the torch frame, changes in speed

prepared by being upsea so that when brought together there will be an excess of metal on both sides. This excess, while slight is necessary to enable the machine to work without the use of welding rods and solves what promised to be a difficult problem. These ma-

FIG. 3. MACHINE FOR WELDING BARREL BODIES, USING OXY-ACETYLENE FLAME ON BOTH SIDES OF JOINT.

machines which enable comparatively unskilled labor to produce entirely reliable work. The barrel welding machine is illustrated in Figs. 3 and 4, and consists of a work holder and a torch holder, the former consisting of a short column which carries two radial arms on which the barrel bodies are supported in a horizontal position, the arms

being necessary to suit a variety of weights of sheet metal. When the body on one arm has been welded, the double arm is swung around a half circle when welding proceeds on the second body, the first body being removed and a fresh one placed in position. In this way continuous

chines are now in actual use accomplishing efficient welding at a speed of from 12 to 20 in. per minute, using two standard water-cooled torches.

A considerable departure from the ordinary run of welding work is shown in

FIG. 4. DETAIL VIEW OF TORCH CARRYING APPARATUS ON BARREL-WELDING MACHINE.

swinging round in a horizontal plane so that each body is brought into line with the torch frame in turn.

The torch frame, Fig. 4, consists of a U-shaped member supported horizontally and working in slides on the side

operation is assured. A typical barrel body will be a sheet of steel 3-32nd in. thick bent to form a hollow cylinder. The edges are previously

FIG. 6. COMPLETED HEATER UNITS WITH WELDED JOINTS THROUGHOUT.

FIG. 5. USING CIRCULAR CUTTING TORCH FOR MAKING TUBE HOLES IN HEADER.

Figs. 5 and 6, the job here shown being large steam heater coils, a number

of which were constructed by the company for use in oil refining. These heaters were about 10 ft. in diameter by 7 ft. high, and consisted of a 4-in. heater top and bottom connected by numerous 2-in. tubes. The holes in the 4-in. headers were all cut with an oxy-acetylene circular cutting torch, the total number of holes being 1,488. Fig. 5 shows the cutting of the holes in the headers, and Fig. 6 shows the complete heaters.

The assembling of the heaters was done by suspending the upper head from a crane when the 2-in. pipes were placed in position and several of them tacked to both headers with the welding torch to maintain position and alignment. The welding of the pipes to the bottom header was first completed after which the coil was inverted and the opposite ends of the pipes welded to the other header.

The time and gas consumed were as follows: Cutting time, each 2-in. hole, 1 min.; oxygen for ditto, 1.25 cu. ft.; acetylene for ditto, 2 cu. ft.; welding time, each 2-in. pipe, 10 min.; oxygen for ditto, 6.2 cu. ft.; acetylene for ditto, 5.4 cu. ft. The circular cutting torch used oxygen under 20 pounds pressure and the weighing torch used acetylene under 6 pounds and oxygen under 14 pounds pressure per sq. in.

#### FOUNDRYMEN'S CONVENTION AND EXHIBITION

CONCURRENT with the Annual Meeting of the American Foundrymen's Association and its affiliated Exhibition at Cleveland, Ohio, from September 11 to 15, the American Institute of Metals will hold its annual sessions at the same time and place. The following tentative business programme has been arranged by the latter:—

"Reclamation of Metallics from the By-products of Foundry and Manufacturing Plants," by A. F. Taggart, Hamman Laboratory, Yale University, New Haven, Conn.

"Method of Selling Non-ferrous Scrap, as Pursued by a Large Producer," by J. M. Bateman, Western Electric Co., Cleveland, Ohio.

"The Results of Joint Work of Casting and Testing the 88-10-2 Alloy by Five Foundries, Report of the Use of the Deoxidizers of Bronzes, and Report on the Aspects of Bronze Failures," by various experts affiliated with the U.S. Bureau of Standards, Washington, D.C.

"Copper-Aluminum-Iron Alloys," By W. M. Corse, Titanium Alloy Mfg. Co., Co., Niagara Falls, N.Y.

"Tests on Rolled Brass Sheets Taken in the Direction of Rolling and at Right Angles to These Directions." By W. B. Price and P. H. Davidson, Scovill Mfg. Co., Waterbury, Conn.

"The Application of Oxy-Acetylene Welding Process in the Repair of De-

fective Non-Ferrous Castings." By S. W. Miller, Rochester Welding Co., Rochester, N.Y.

"Continuation of Discussion in Connection With Defective Bronze Castings In Use By the Board of Water Supply of New York City." By A. D. Flinn, Board of Water Supply, New York City.

"Evolution of Die Casting Process." By Chas. Pack, Doehler Die Casting Co., Brooklyn, N.Y.

"Disclosure of Blow Holes by Means of X-Ray Apparatus." To be reported by testing engineers employed in laboratory D of the General Electric Co., Schenectady, N.Y.

"Aluminum Castings and Forgings." By P. E. McKinney, U.S. Navy Yard, Washington, D.C.

"Annealing Properties of Copper." By G. W. Ceasor and G. C. Corner, Hammond Laboratory, Yale University, New Haven, Ct.

"Metallography as Applied to Non-Ferrous Metals." By W. W. Arthur, Frankford Arsenal, Frankford, Philadelphia.

"Heat Treatment of German Silver." By C. C. Holder, American Optical Co.

S. D. Sleeth of the Westinghouse Air Brake Co., Wilmerdene, Pa., and Mr. Barnes of the Fort Wayne Electric Co., Ft. Wayne, Ind., will present papers at the session to be devoted exclusively to the discussion of brass foundry practice and papers also will be read by F. L. Antisell, Rariton Copper Works, Perth Amboy, N.J., and by Mr. Bragg, Ohio Brass Co., Mansfield, O.

#### Entertainment Features

These will consist of a trip to the ball park, Tuesday afternoon Sept. 12, to witness the game between Cleveland and Detroit; a trip to Euclid Beach Park, Tuesday evening, Sept. 12 in special cars where tickets to all concessions will be furnished; an inspection tour to the Cleveland Furnace Co. plant, Wednesday afternoon, Sept. 13, and a theatre party at Keith's Hippodrome, the evening of Wednesday, September 13. The ladies will be tendered a luncheon at the Hotel Statler, and also will be given an automobile ride. The annual banquet will be held Thursday evening at the Hotel Statler, and Irving Bacheller, the noted humorist, will be one of the speakers. Plant visitation will be limited to Thursday and Friday, Sept. 14 and 15, arrangements having been made for the inspection of the plants of the Ferro Machine & Foundry Co., the Allyne-Ryan Foundry Co., and the Westinghouse Electric & Mfg. Co.

#### PLACE AND PURPOSE OF INSPECTION DEPARTMENT

IN the majority of factories, says F. B. Corey, in the Dodge Idea, the inspection department is under the authority of the factory manager or superintendent.

in other words, that branch of the organization which builds the apparatus, and decides whether that apparatus is properly built. It is unnecessary to point out the inherent weakness of this arrangement.

#### Liability to Biased Judgment

The judgment of the inspector may continually be biased by the fact that he is a part of factory organization and is responsible to the factory management. It is, therefore, evident that the highest standards of quality and workmanship can hardly be maintained continuously if the members of the inspection department are in any degree subject to the control of a factory superintendent or any other executive who is directly responsible for the factory production and has no connection with the engineering or sales organizations. This statement should not be understood as expressing a doubt in regard to the loyalty or honesty of purpose of any factory official. We must recognize the fact, however, that defects, due to drawings or specifications, are often disregarded by inspectors if they know that no criticism can be attached to them by their superiors on account of the latter's approval of the apparatus, especially when a rejection would prevent meeting a promised date of delivery.

In a smaller number of shops, the inspection department is under the control of the chief engineer. With this arrangement, the judgment of the inspector is likely to be biased by the fact that any defects in the finished product, due to improper specification of materials or any failure of the apparatus to function properly, might be considered as reflecting on the abilities of the engineering department. The inspector will often hesitate to reject a device if he thinks that the objectionable feature may be attributable to his superior officer, as it would imply a difference of opinion that might reflect discredit on the inspector's judgment. Moreover, there is often a tendency among young and subordinate engineers to refuse to recognize slight defects in a design for which they are personally responsible, and to severely criticize an inspector who points out what he considers a defect in such apparatus. Therefore, it will be seen that in most cases the executive head of the inspection department should be as free from control of the engineering department as from the manufacturing department.

#### Inspection Head Responsibility

The only logical plan of organization is that in which the head of the inspection department, whatever may be his title, is responsible directly to the general manager of the company or the chief executive in control of the factory output. He should report to the same officer as the works manager or the chief

engineer. At the same time, he must be in full sympathy with all other departments. He must command the respect of the other department heads and be ready to co-operate with them to further the interests of his company.

The executive head should exercise a most thorough control over all the activities of the department. To that end, there should be no recognized paths of communication between this department and the heads of the other departments, except through his office. The strict enforcement of this rule is essential to the efficient working of the department and to the avoidance of misunderstandings and duplication of effort. This requirement, if rightly understood, will not be interpreted as limiting the useful activity of any member of the department, but will be recognized as a necessary feature in the conduct of inter-department business.

#### Chief Inspector's Qualifications

The executive head of the inspection department should be thoroughly familiar with general engineering practice and standards. He should be well informed on all shop methods, including foundry and machine shop practice, and be thoroughly versed in the use of testing machines and gauges. He should, if possible, be conversant with chemical laboratory methods and apparatus, so as to be able to direct intelligently that part of his organization. Moreover, he should be familiar with the uses of the factory product and the conditions under which it is to operate after it has passed beyond the control of the factory. He must have absolute control of every inspector in the plant, and be held responsible for the quality of material and workmanship of all that the plant produces.

#### Customers' Complaints

In the majority of manufacturing corporations, all dealings with the customers are conducted by the sales department exclusively, which is the logical arrangement. For this reason, complaints on the part of the customer are made directly to the sales department and usually reach the shop through a more or less tortuous channel. There is sometimes a tendency on the part of the sales department to assume that all of these complaints are justified, to criticize the shop for turning out an unsatisfactory product, and especially to blame the inspection department for failure to prevent the issuance of the material in question.

In justice to all concerned, including the sales department, all such complaints should be referred to the executive head of the inspection department for a personal investigation and report, and action on the part of the sales department, except so far as it relates to the replacement of material urgently

needed, should be deferred until the report is in hand. This report may entirely change the attitude of the customer with relation to the alleged defective material, as it may clearly show that its failure to meet his expectations was due to no fault of the manufacturer or of the apparatus involved.

The trouble may have been due to injury in shipment, rough handling after receipt, failure to install or to apply it properly, lack of proper maintenance on the part of the customer or his employees, or to a misconception of the capacity or function of the apparatus itself. Any errors on the part of the factory or inspection department must be freely acknowledged and any steps to prevent their recurrence should be fully explained. An unbiased report, based on all the available facts, rendered by the head of the inspection department to the head of the sales department, may be invaluable to the salesman in his negotiations with the customer.

The inspection department exists for the mutual protection of the manufacturer and the customer. The salesman should be informed in regard to the methods and practice of the inspection department, as this knowledge may be of great service in promoting friendly relations with a prospective or actual customer. The customer is often much interested in the means employed to ensure accuracy in the manufacture of the apparatus he proposes to use. The head of the inspection department should, therefore, make it his duty to advise the sales department of any change in procedure or equipment that might be of interest to that department in its dealings.

The relations of the inspection department to the engineering department are most important, especially in the influence that may be exerted on the designs for new apparatus and the improvement of the old. In many places, new drawings, when completed and before their final approval, are submitted to a committee (variously known as "mechanical design committee," "limit committee," "standard committee," etc.), to determine if the limits set by the designers are such as can be met commercially in the factory, and to decide if any changes are desirable on account of methods to be used in the foundry, machine shop or elsewhere.

The head of the inspection department should be one of the most important members of this committee; in some instances he is chairman. His principal duty in connection with this committee is to advise if the dimensions, tolerances and limits called for on the drawings are satisfactory for the various fits, and if the quality of finish called for will be satisfactory to the inspection department. Thus the work of the inspection

department should begin even before the designs are approved for manufacture.

#### Inspection Department Organization

The internal organization of the inspection department and the means and methods best adapted to carry out the details of its work are matters that will depend to a great extent on the management and operation of the larger manufacturing organization of which it forms a part. A plan of organization that may be highly efficient in one factory may be deficient in meeting the needs of another shop producing a different product or producing a similar product by widely different methods. The organization of inspectors that is perfectly suited to a factory having a large output of a few well standardized articles would be wholly unable to cope with the situation arising in a smaller factory producing a great variety of articles, but making each in comparatively small number. It is obviously absurd to try to apply big-shop methods to a small shop, and the converse application, while far more usual, is no more logical. Such matters must, therefore, be subjects of careful investigation and study in each individual plant.

#### CONTRACTION CAVITIES IN SPUR WHEEL BLANKS

THE following query appearing in a British contemporary is of more or less interest to readers of our journal, some of whom may have been up against a like trouble; on the other hand, there may be those who are prepared to suggest a solution.

I am having trouble with certain Government work which is really very simple from a moulding point of view, namely, spur-wheel blanks. The teeth of these are cut, of course, after they are turned and I find in many of them liquid contraction or gas holes at the rim where the arms join. (These are mostly of H section.) To get rid of contraction I introduced "chills," at the corners of the arms, and found that for a while I quite got over the trouble at that point, although it seemed then to move midway between the arms.

The larger wheels (some exceed 1 ton) are moulded in the floor and the arms are cored out in the usual way. The mould is made of dry sand and is dried in the floor; the smaller ones are taken to the oven and dried, cast from the hub, with four risers on the rims. The wheels generally have six arms. A feeding rod is placed in the hub, and also in the risers. The metal we use taps out at:—Carbon, 3.40; silicon, 1.9 to 2.5; sulphur, 0.6; manganese, 0.6 to 0.8; phosphorus, 0.80 to 1.2.

I have tried green sand also, but the percentage of wasters is about the same. I would be pleased to have a suggestion for a solution of the difficulty.

# PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data  
and Ideas Evolved from Actual Practical Application and Experience

## FIXTURE FOR SHEARING PINS.

By F. M.

HAVING a large number of pins to cut-off and nothing suitable for doing the job, the fixture shown in the accompanying illustration was devised. It is practically a shearing punch and die in a suitable holder which can readily be adapted for various sizes of wire. This tool consists of the base A drilled out at C and D to allow the wire to pass through; the bushing B is to guide the wire and is of steel hardened to form a die; the long plunger E is the punch, and the die and punch are both flattened at F where they come in contact for shearing.

In operation, the plunger E is struck with a hammer which shears the wire off against the die when the plunger is returned to its original position by spring

FIXTURE FOR SHEARING PINS.

G. The plunger is prevented from springing out of the hole by screw H. This makes a very rapid method of cutting off pins and does not wear the hands as would a pair of heavy shears.

## HOLDER WHICH SAVES ERASERS.

By H. Scriber.

A HOLDER which proves very economical in the use of erasers especially for drawing is shown in the accompanying

HOLDER WHICH SAVES ERASERS.

illustration. The idea of this holder is to permit the eraser to be cut in half lengthwise, then taking one half of the eraser, place it in the sheet metal holder A, which is steel, spring tempered, thus binding eraser at X. The holder securely grips the rubber at the end. The eraser being narrower and stiffer than

an ordinary rubber without the holder, it permits of more pressure being placed on the eraser, and also allows the user to better see the lines being erased.

## CHART FOR FINDING WEIGHT OF CAST IRON PIPE.

By N. G. Near.

THE accompanying chart will be found useful for determining the weight of cast iron pipe or cast iron columns. It is not necessary to do any computing at all. For example, what would be the weight of a cast iron pipe 30 ft. long,

feet. For rough estimating work this chart will be found hard to equal.

## MOLDING HAND GRENADES

By Allan Hill.

THE hand grenades which are being used to an enormous extent in the present war are of various types, but are generally round or oval in outline, and are made of various materials. The most destructive have been proved to be those made of cast iron, and molding of which is here described. The weight

CHART FOR FINDING WEIGHT OF CAST IRON PIPE.

with a dimension D of 24 inches, and a thickness of one inch? The dotted lines drawn across the chart show how it is done. First connect the 30 (column A) with the 1 (column D) and locate the intersection with column B. From this point of intersection run straight to the 24 (column E) and the result is found in column C. The weight is practically 7000 pounds.

It will be noted that the range of the chart is very wide and will give the weight of a total length of all ordinary sizes up to 1000

varies in different designs, but each design must be kept to its given weight, so the best method of molding is by machines, which keeps them to a perfect shape as well as a correct weight, and is more sure than ordinary pattern-plate molding on the floor.

## Large Outputs at Low Cost.

The making of these grenades involves large outputs at low costs, and, as large numbers of foundries are engaged in their manufacture competition is very keen. The biggest proposition is

in obtaining the cores. They are not difficult to make, but if ordinary methods are used a large amount of labour is required, for one molder will use more in a day than one core-maker can make in two days.

The sand must be such as to make a solid core that can be handled without damage, allow free venting, leave a smooth skin on the inside without having to resort to the use of blacking, and also enable the core to be removed from the casting whilst in the tumblers. Oil-sand mixed in the right proportions will be found to be the most satisfactory, as it will fulfil all the conditions mentioned, the following being the mixture used:—1 barrow of dry rock sand,  $\frac{1}{4}$  barrow of sharp sand, 1 quart of boiled linseed oil. These must be thoroughly mixed. The mixture being given its working degree of dampness by the addition of water. The core-boxes also must be kept well oiled with paraffin, and kept warm; if this is not done the sand will adhere to the box.

#### Molding Methods Employed.

Various methods of molding have been adopted, each establishment using its available appliances, converting them for the purpose and no doubt following its own practice as far as possible. The following are the methods used in a large Lancashire foundry, where quantities of two types are being turned out, one a round one, the other an oval one which goes by the name of "Mill's" grenade.

For the round grenades two series of machines are used, Farwell hand presses and stripping-plate machines made by the Adaptable Molding Machine Co., on which the molds are hand-rammed. In both cases the patterns are mounted so that cope and drag are rammed from the same face, using one pin and one pinhole in both cope and drag. On the "Farwells" a 12 in. by 12 in. snap flask is used, four castings being made in one flask. No bands are used for casting, a heavy flat weight with an opening for the runner being placed on the top of the mold.

On the "Adaptable" machines, cast-iron boxes are used, with eight castings in one mold, the boxes being 18 in. by 12 in. These are shown in Fig. 2. On the pattern face are thin pieces of wood leading from the centre of the core print to the outside of the mold, being ventways to carry the air and oil gases away. On all molds for this class of grenade, a small vent wire is pushed through the top to conduct the air from the mold, so the castings may be run very quickly, the ingate being placed on the side of the casting. The facing sand used is a mixture of equal parts of best red, yellow brass, and old floor

sand, with the addition of 1-20th of the whole bulk of coal dust, the whole being well ground and mixed before using. This does away with dusting the molds with facing, the sand coming away from the castings quite easily and leaving a very smooth skin.

#### Core Feature.

The cores are shaped like a dumb-bell, one core thus being used for two castings. In the centre of the print is a small raised piece which coincides with one on the pattern, this being done so that the core can be set by simply dropping it into the print, the raised piece preventing it from being placed further into one casting than the other (which would alter the weight), besides doing away with the use of templates for setting. The ventway before mentioned also leads away from this part of the core.

Each core-box is made in three portions, two being the box proper, the other a dummy part. They are made as follows:—The bottom half is rammed with sand and the core-iron and vent-wire placed in position, then the dummy part placed in position and also rammed up. After taking away the dummy, the core is left, the core being given its correct shape by putting on the other part and giving it a few smart taps with a wooden mallet. The vent-wire is now withdrawn, the core released from the box, and the hole made by the wire made up, as a passage for the escape of gas is formed by the small stud on which the wire rests whilst the core is being rammed. This method gives a core that is perfect in size and shape, and does away with making the core in two halves and pasting them together. By using the first method, cores could be made at about twice the rate of the pasting method.

#### Oval Grenades.

For the oval grenade, the "Adaptable" machines are used and also the same type of boxes, but with 12 castings in one box. These grenades have 12 grooves running from top to bottom, and also three round the body, the latter being formed in the machine shop, so the castings have to be made on their ends, one core for each, which is set by template. To get gas away from core, a wire is pushed down every print, also underneath the boxes. A vent is made through the top of the mold to conduct away air in the mold.

The core-box from which the cores are made is somewhat of a novelty. It is in two halves, hinged on one side, and, when closed, is secured by a catch. Into one half a hole is drilled in which is placed a spring strong enough to force the box open when the catch is released. To use the box it is closed and the sand rammed through the print until

the box is filled, a core wire inserted and also vented. After tapping very lightly the core-box is turned over and the catch released, allowing the box to spring open, leaving the core intact. Before using this spring the core has to be turned out on the hand, for if the box be opened on the bench the core is generally knocked over or remains fast in one half. The sands, both facing and core, are the same as for the round grenades.

The iron for these grenades must be close, but also easy to machine; and as they are very thin in section suitable irons must be used that will not chill on the edges which have to be machined. The following irons are used in the particular case under consideration:— $1\frac{1}{2}$  cwt. Staveley No. 3;  $1\frac{1}{2}$  cwt. Glengarnock No. 3; 2 cwt. Thorncliffe No. 3; 6 cwt. good machinery scrap. As no complaints have been received in connection with this, it can be taken as being as satisfactory as any other for this class of casting generally.—Foundry Trade Journal.

#### SCRAPPING VS. REPAIRING

AN English author has characterized the American manufacturer as a man 'who scraps instead of repairs,' says a writer in the Woodworker. Whether this is considered as a criticism or a compliment depends upon the point of view. With more expensive labor, the American manufacturer has been compelled to look for enough efficiency in his machinery to overcome this handicap and to meet competition. It has often been cheaper for him to scrap an old machine and install a late model that would increase his production. In fact, some of the most successful manufacturers have not hesitated to scrap comparatively new machines, when investigation showed that a newer type would materially increase production.

The man who holds the coin so close to his eye that it eclipses everything else, is not exactly a stranger, though rapidly dropping out of sight. The successful man is the one who holds the coin at a distance that allows a proper perspective, and hastens to spend it when his judgment assures him that the spending is really an investment.

It oftentimes requires courage and patience to wait for opportunity, but it is worth not only working but waiting for, and initiative and good practical ideas, combined with energy and enthusiasm, are sure, sooner or later, to bring their just reward.

There are 73 buildings, large and small, used for exhibit purposes at the Canadian National.

### Forge Department

A row of hydraulic forging presses is arranged down the centre of the forge shop. Each furnace serves a separate press. From a point above the furnace outlet door to a point on the press structure a stout wire rope is stretched. On this runs a pulley from which a chain depends. To the chain a pair of tongs is attached. The white hot billets can thus be readily and quickly, one at a time, pulled out of the furnace and carried over to the press. On the way across any scale formed on the surface of the billet is knocked off with pointed bars of steel. The corners of the billet as received are rounded off so that the length across the diagonals is about equal to the diameter of the forging. This permits the billet to be readily slipped into the round mould or container. It will be noticed that the length of the forging is slightly greater than that of the billet.

The hydraulic presses are operated by water under a pressure of 1,200 lbs. per square inch. They are of the vertical type and consist of a bed-plate, upon which four pillars are erected. The main hydraulic cylinder, which does the forging work, is inverted, and is carried by these four pillars. The bed-plate also carries a pair of guides upon which there runs a carriage carrying two large steel pots, within each of which is placed a steel mould or container. The carriage with these pots is moved to and fro on the guides by a horizontal hydraulic cylinder. Each pot alternately can thus be brought under the forging cylinder.

At each end of the bed-plate a small vertical hydraulic cylinder is sunk into the ground. The rams of these cylinders are used to eject the finished forg-

ings from the mould in which they have been formed. It is necessary to provide this power because, after forging, the metal being expanded tightly against the walls of the mould, is apt to stick. It is arranged that when pot A is under the forging cylinder pot B is over its ejecting cylinder. Thus, while one billet is being forged the preceding one is being ejected.

The ejector ram when it rises enters a hole in the bottom of the pot. Rising further, it enters a similar sized hole in the bottom of the container or mould. This hole just fits the diameter of the

FIG. 2. SHELL BILLET AND FORGING.

ejector ram and is smaller than the diameter of the finished forging. In sections, therefore, the container or mould shows a round bore of diameter equal to that of the forging and is carried to a depth which exceeds the length of the untouched billet by a short amount. At the foot of this bore comes another one of smaller diameter, equal to that of the ejector ram. On the circular step thus formed a round plate rests loosely. This supports the bottom of the shell while it is being forged, and can rise on top of the ejector ram when the billet is forced out of the mould.

### The Forging Process

There are two punches on each press,

these being mounted on a slide which can be moved in a direction at right angles to the guides on which the pots run. Just as these pots are brought alternately beneath the forging cylinder, so, too, are the punches. The two punches are so connected that they move in unison. Thus, when punch A is being forced by the ram of the forging cylinder into the billet, punch B is also descending. In so descending it passes into a pot of water where it is cooled. It is then ready to be moved across into the forging position and to deal with the succeeding billet. It will thus be seen that while one billet is being forged the preceding billet is being ejected and the succeeding billet being got ready in position. Simultaneously, the punch for the surrounding billet is being cooled.

To permit the punch to be withdrawn from the shell without dragging the shell out of the mould, two bars are fixed across the top of the pot at a distance apart which will permit the container or mould to pass between them as is required when the mould has to be replaced. When the forging is over, except for the withdrawal of the punch, a vee-shaped block of steel is slipped beneath these bars. The limbs of this block pass on either side of the punch. The bottom surface of the block rests on top of the mould and overlaps the lip of the shell. With this block inserted, the punch can be withdrawn, the block and the bars meanwhile holding the shell down.

### First Inspection

Immediately after forging, the shells are inspected, and if found in order, passed and stamped by Government inspectors. An interesting mechanical device is in use to assist in the inspection

FIG. 3. VIEW IN A BRITISH NATIONAL SHELL FORGING PLANT.

process. It is intended to detect any shells which have been forged eccentrically. Precautions are taken at the presses to see that the punches and moulds are correctly aligned, but even so eccentrically forged shells are sometimes turned out.

The device referred to is sketched in Fig. 4. A is the end of the shell. B is a lever, one arm of which is provided with a roller which rests on the surface of the shell at a point near its closed end. The other arm of the lever is a pointer. The shell is slipped over a power-driven spindle C, which just fits its bore. When it is rotated, the end of the pointer must not pass outside two gauge marks D inscribed on a board fixed behind the pointer. If it does, the shell is too eccentric to be passed. The eccentricity is thus examined at the closed end of the shell. If there is any eccentricity it will be most marked at this point. The device enables a large number of shells to be inspected in a very short time.

#### Upkeep and Labor

The containers, the punches and other parts of the presses have frequently to be renewed. The renewals are made and carried through by the staff of the tool room, the situation of which is shown on the plan. Beyond the tool room is the pump house, which supplies the pressure water used by the forging presses. Here are to be found electrically-driven pumps, each with three rams and all delivering into an accumulator. The current to the motors driving the pumps is controlled automatically in such a way that as the demand for water increases or decreases more and more of the pumps start or stop working.

A word may be said in conclusion regarding the staffing of the forge departments. At present no female labor is employed in the forge itself, nor is it probable that it will be in the future, at least in the forge proper. The heat here is somewhat trying, and it is believed that male labor alone is suitable. The men actually employed were all quite untrained for the work to begin with. On the average, however, fourteen days is found sufficient for instructing them in their work.

The tool room is staffed by both male and female labor. The portions of the presses actually coming into contact with the hot billets require very frequent renewal, particularly so in the case of the punches and their components. Arrangements have, therefore, been made for the production of these articles on the principle of specialized working, and the greater part of this work is carried out by women. The renewal of parts of the valves, however, and other delicate adjuncts of the presses remains in the hands of skilled male workers, who are

also responsible for the management of the workshop and the instruction of the women.

#### DON'TS FOR THE GRINDING MACHINE OPERATOR

Howard W. Dunbar.

(1)—Don't attempt to grind without using the proper number and proper application of steadyrests, if you wish the work to be round, true and smooth.

(2)—Do not expect to get round work without round centre holes in your work and true centre points in your machine.

(3)—Don't attempt to grind without a quantity of good lubricant flowing over the work and wheel at the point of contact between wheel and work.

(4)—Don't put too much compound in the water; the proportion should be about 40 to 1; too much compound causes undue foaming.

(5)—Don't allow compound to foam and froth and run all over the machine and the floor. This can be reduced by sprinkling a little kerosene on the foam

FIG. 4. DEVICE FOR TESTING ECCENTRICITY OF SHELLS.

in the top of the tank, or by adding several pails of clear water.

(6)—Don't thin the compound so much that there will be no rust preventive in the water; if you do your machine will become rusty and corroded.

(7)—Don't use hard wheels; soft wheels give greater production.

(8)—Don't forget to oil the machine thoroughly at least once each day, preferably on starting up in the morning.

(9)—Don't use "any old oil" on the wheel spindle. Special spindle oil is provided for and necessary, due to the amount of clearance left between the diameter of the spindle and the diameter of the box, where clearance must be just filled by the oil used. Therefore, the oil must be of the proper grade and viscosity to accomplish this object.

(10)—Do not worry if the wheel spindle runs warm or cold, so long as it grinds round, perfect work.

(11)—Don't attempt to take too deep cuts; lighter cuts and more of them will produce as much work and still keep the wheel true and in better shape for a greater length of time. Still you must use good judgment; excessively light cuts will permit the wheel to glaze over and not cut properly.

(12)—Don't forget that a generous use of the diamond yields large returns in dollars and cents.

(13)—Don't attempt to grind round work with a wheel that is out of balance. You should try the wheel for balance as it wears down; one balancing is not sufficient to insure a wheel remaining in balance throughout its entire life.

(14)—Don't try to grind without chatter marks when all the belts on the machine are uneven in thickness and bumping every time they pass over the pulley.

(15)—Don't try to grind work in your machine which is beyond the capacity of the machine both for length and swing.

(16)—Don't remove the wheel spindle of your grinding machine just for examination of the bearings.

(17)—Don't expect perfect bearings in the box of the wheel spindle for such a thing is impossible and unnecessary.

(18)—Don't press the point about the bearing in the wheel spindle box, because if the spindle is round you will get perfectly smooth rotation in a box, even if it only bears at three points.

(19)—Don't say that chatter marks are caused by imperfect scraping of wheel spindle box bearings. Scraping never was and never can be the cause for chatter marks.

(20)—Don't undertake to adjust the wheel spindle boxes unless you have had experience with such work.

(21)—Don't forget that nine-tenths of the trouble in this world is due to ignorance. So if you are not familiar with certain features of adjustment about the machine, don't attempt such adjustments until you are thoroughly acquainted with just how they work and how they are used.

(22)—Don't pound on the swivel table of the machine with tools, hammers, wrenches, etc., to make it move. If you swivel the table through its entire movement and clean it once a week, it can be moved without pounding.

(23)—Don't expect the machine alone to produce a fine finish; there is a good deal in the operator's knowing how.

(24)—Don't forget that the smoother the point of the diamond, the smoother will be the finish on the work.

(25)—Don't think of the diamond as sharpening the wheel, but rather as correcting the surface.

(26)—Don't expect to succeed in quantity or quality of work without having a diamond constantly at hand.

(27)—Don't use a wheel narrower than 2 in. except on special work which requires a narrower wheel.

(28)—Don't expect wide wheels to grind the same as narrow wheels; generally, the wide wheel is required to be a little softer.

(29)—Don't expect the machine to run itself; success in grinding depends upon constant attention and care in the operation of the machine.

(30)—Don't expect to get a "looking-

glass finish" when the wheel is cutting freely.

(31)—Don't run the diamond across the wheel rapidly if you wish a good smooth finish, as such a procedure will cause the wheel to be imperfectly trued and mottle marks are apt to appear on the work.

(32)—Don't run the diamond too slowly across the wheel if you wish the surface broken up so that it will cut freely and quickly.

(33)—Don't complain that diamonds wear out too quickly; diamonds are profitable—whatever their cost—in the hands of experienced operators.

(34)—Don't forget that cleanliness is as necessary at the machine as at our homes. We must wash our faces at least once a day. Why should it be a hardship to clean a machine two or three times a week? A good operator is generally known by the appearance of his machine.

(35)—Don't forget that the greatest mistake a man can make in life is to ignore the experience of an older man.—Grits and Grinds.

## UNORTHODOX PATTERNS

By J. R. Moorhouse.

IT is admitted there should be no excuse for an unworkable pattern, but there are occasions when conditions positively compel the patternmaker to pass on to the foundry patterns that are scarcely worth the name. These add considerably to the foundry costs, and result in unsatisfactory castings—a very questionable economy. Apart, however, from these, a pattern may be quite practicable and leave much for the moulder to do to complete his mould. Of such nature are the "one-off" variety of patterns; and just where the line should be drawn in regard to what should be done in the pattern-shop and what left for the foundry to do, in view of the entire cost, is of itself a controversial subject. When patterns are required for standard work, too much consideration cannot be given to saving labor in the foundry. Such patterns should be built up in the best possible manner for repetition moulding.

It is here where the patternmaker is often in a difficulty. Though expense may be no consideration, time is vital to the making of a reliable and efficient pattern. As ideas are perfected and laid out in the drawing office, there is a rush to get these going in the pattern-shop, so that some tangible result may be seen in the shops as soon as possible. The daily reminder and inquiry, how soon these are to be sent on to the foundry, is no encouragement to thoroughness, neither is it conducive to the best of relations between the foundry and pattern-shop.

## Pattern-Shop and Equipment

Given adequate and up-to-date machinery, arranged to the best of advantage in a well-lighted and ventilated building, the most vital factor in getting out good work and workable patterns cheaply and quickly is ensured. Of a secondary consideration in the make-up of a pattern is the materials used; and although timber will remain the standard for most classes of work, against which no other material can possibly compete, there are occasions when plaster-of-Paris can profitably be used for the quick production of patterns, not for the saving in the price of the material, but rather because it so readily can be worked up into intricate shapes that otherwise would require considerable labor if worked out in timber.

### Plaster-of-Paris in Pattern-Making

To the wood pattern-maker this necessitates what, to him, are unorthodox methods of procedure in pattern construction. The use of plaster-of-Paris in the pattern-shop, as is well known, is not new; the writer in his early apprenticeship worked plaster for patterns. It was then used for making accurate forging-tool patterns, one example being a railway carriage draw-bar hook. A model of the hook to be forged is first made in halves in wood. This is then passed by the inspector to check all sections, etc. A frame is next made to conform to the dimensions of the forge block required, and deep enough to leave  $\frac{1}{2}$  in. of plaster at the shadow portion covering the hook face: nails are then driven in the inside with the heads protruding well out, to form an anchor for the plaster. One half of the hook, which has previously been varnished and thinly smeared with oil, or preferably vaseline, is secured to a board, on which is placed the frame, over and in correct relation to the hook. Having made this secure, the plaster is run in and strickled flush with the frame edges. In a few moments the board can be inverted and the hook carefully withdrawn, leaving a perfect impression of the hook in the plaster pattern.

It needs no argument to show how much quicker this can be accomplished than working the hook by trial and error into a wood block. To form the top stamping block the process is very much the same, with the exception that the two halves of the hook are placed together as a means of registering the top in true relation to the bottom, so that the stampings will not be overshot, being then put back in the already half-formed plaster pattern, on which is fixed the mating frame for retaining the plaster forming the top half block. This is weighted and then run in with plaster. When set it can be carefully removed, leaving a true impression of the model.

The same procedure is often followed in jobbing lines of valves and intricate inlet pipes, etc.

### Strickle Work and Plaster-of-Paris

A little experience is necessary, especially on strickle work to manipulate the plaster to the best advantage, as when once it commences to set it cannot be restored without seriously impairing the strength of the pattern. The amount of plaster to use to a given quantity of water varies according to the nature and grade of the material, as also the temperature of the room in which plaster patterns are to be made. A good method is to lightly and quickly sprinkle the plaster over the whole surface of the water, until it begins to settle on the surface. This is then thoroughly mixed, preferably with the hand, until it has a creamy nature, when it can be then run off. For strickle work it may be necessary for the first coat to run it a trifle stiffer, and thinner on the finishing layer. These, however, should follow immediately, if possible, one on the other, to form a bond for the best results. Especially is this necessary on thin strickled sections, where it is found impossible to complete it at one operation.

It should be mentioned that a useful material for working along with plaster-of-Paris, and which widens the field of application for pattern construction, is plasticine, a class of modelling clay. With this material, holes or pockets can be readily formed in plaster moulds, in the same way as cores are used in the sand mould.—From a paper before the Lancashire Branch of the British Foundrymen's Association.

**Protection of Iron by Enamelling.**—A method of enamelling iron, consists of the following:—The metal is first pickled in hydrochloric acid to free it from foundry scale, then washed thoroughly and dried. The first coating applied is composed of 34 parts silica, 2 parts soda, and 15 parts borax, mixed in water. The metal thus coated is exposed for 10 to 15 min. in a dull red-hot retort. A second coating is then applied, consisting of 34 parts feldspar, 19 silica, 24 borax, 16 oxide of tin, 4 fluorspar, 9 soda, and 3 saltpetre. This mixture is first melted in a crucible, then ground to a fine paste in a little water and applied with a brush. The coated piece is then again subjected to white heat in a muffle. It is claimed that the enamel unites with the iron and that pipes thus enamelled have been in use for many years without deterioration.

All exhibits at the Canadian National Exhibition from foreign countries are admitted by the Customs free of duty.

## MACHINISTS' INSTRUCTION COURSE—I.

By J. Davies.

**T**HE machinist or engineering trade is one that any young man might well be proud of, it offers unlimited scope for the display of inventive genius and calls forth the highest degree of skill and sound judgment, an error of one thousandth part of an

FIG. 1.

inch being taken quite seriously in some of our Canadian high grade tool making establishments. The ordinary lathe hand is expected to be able to work within five thousandths of an inch as that amount more than represents the difference between a loose and tight fit.

### Commencing Studies.

The first advice I would offer to the boy entering the machine shop is to join some evening school technical class, where he can acquire a knowledge of machine drawing and construction and workshop mathematics. Although it will be some time before he is called upon to work from a blue print it is a good plan to begin to learn reading a drawing as soon as he enters the shop, then when the time comes that he is expected to work from a blue print he will not have to be continually chasing the foreman around to know what every little thing means. If you think you are a smart boy don't let the men know that you think so. A certain amount of confidence in your own ability is necessary for your success, but don't let that confidence develop into conceit. You may expect to be fooled a few times by being sent after the left-hand monkey wrench, or some other tool that only exists in the imagination of the man who sent you after it. When you find that you have been the victim of a practical joke, don't get angry, anger does not improve anything except the arch of a cat's back; take it as a part of your workshop education and you will soon make friends.

### Regarding Left Hand Tools.

Don't imagine because you were fooled on being sent after some imaginary left hand tool, that there are no legitimate left hand tools. There are left hand dies, taps, side cutting tools for lathe planer and shaper, cutting off tools, knife tools, threading tools, hobs used on milling machine and gear cutter for making worm wheels. Remember

FIG. 2.

that a left hand side tool or knife tool is bent toward the right and is called left hand because it is used for cutting the left hand side of the work or job that is in hand, see Fig. 1.

To distinguish a left-hand tap or thread take a pencil point, a nail, a piece of wire, or anything that is handy. You do not need an elaborate kit to place the point in the thread somewhere about the centre and move it around the thread clockwise—if your hand travels towards the top it is right hand; if towards the bottom it is left hand. Make a sketch of a left and right hand thread and fix it definitely upon your memory. If the thread inclines upward from left

FIG. 3.

to right it is right hand, if it inclines downward from left to right it is left hand, see Fig. 2. A little study of this will fix it definitely upon your memory and you will find it a very useful thing

to be able to distinguish right from left at a glance.

The only exception to this rule is a sectional elevation of a nut or internal thread such as a thread inside a hand-wheel. When an internal thread is shown in section it reverses the angle, because you are looking at the opposite side of the thread to what you are in elevation or outside view. It is here illustrated by making a section of the threaded boss of a press, see Fig. 3, in which it will be seen that while they are both right hand, the angle of the sectional elevation inclines in the opposite direction to the screw. The amount of the inclination is equal to half the pitch, that is half the distance of one thread from the other.

### Get Tools of Your Own.

Study in order to become familiar with all ordinary shop tools and their uses. Plan to get some tools of your own as soon as possible as the youth that is always running around borrowing and returning tools soon gets in

FIG. 4.

FIG. 5.

disfavor with both men and masters. You do not need an elaborate kit to begin with—a hand hammer, a combination set comprising square, bevel protractor, spirit level, and centre finder, and a 12-inch scale with square ends graduated on 4 edges, a 6-in flexible rule, a pair of dividers and a small pair of inside and outside calipers. Combination tools are more likely to be inaccurate than tools made for a single purpose. When buying a combination set, have them tested in the workshop and if you find them inaccurate to any appreciable degree the makers will gladly exchange them and thank you for calling their attention to the fact. It is not often that you will have any room for complaint if you buy your tools from some well known maker, but

it gives you more confidence in your work if you know that your tools are correct.

Test your tools as follows:—(the method here described for testing your tools can be applied to a great variety of other jobs). Testing a combination square,—put in your 12 in. blade as shown in sketch 8, Fig. 4, taking care that there is no dirt or grit in the slot of the stock where the blade goes in, place the base of the stock against the planed edge of a surface plate or marking off table then make a fine line close up against the blade, reverse your square as shown, and draw another line parallel with the first one, leaving just as small a space between the two lines as the eye can detect, or you may draw one line exactly on the top of the other. If the two lines thus drawn run exactly parallel your square is correct, if the lines do not run parallel the error in your square is equal to half the error shown by the lines. Now take out the blade and turn it upside down to test the other edge, or you may try it with micrometers to see if it is parallel which amounts to the same thing.

#### Testing Tools.

To test your center finder, you practically repeat the same operations, except that instead of the surface plate, or marking off table, you must get something that is perfectly round. The end of a short shaft turned and faced in the lathe, or the end of a plug gauge will serve very well, the diameter being such as will allow the sides of the center finder to bear somewhere about the middle, see Fig. 5.

To test a spirit level place it upon the surface plate, and pack up the plate, not the level, until the level shows perfectly level, then draw a pencil mark around the edge of the base of the level, reverse the level placing the base inside the pencil marks, and if the level still shows true it is true. If you are testing an adjustable level, adjust it until it fulfils the conditions as stated. If your level is not adjustable then you will have to scrape, file, or machine the base of your level to correct any error there may be in it.

To test your protractor—Since there are 360 degrees in every circle, if two lines forming a square or right angle are placed inside a circle, they will divide that circle into exactly four equal parts, and as 360 divided by 4 is equal to 90, the angle of the square will be 90 degs. Therefore set your blade at 90 degs. and test exactly as you did for your square, if the base of the stock does not form a perfect square with the edge of the blade, it follows that every other angle will be out an equal amount.

### ERECTING AND OILING THE LATHE

THE following observations are taken from the Lodged Shipley "Lathe Operating Manual." They will be of interest to our readers not only on account of the primary intention, but because of their application to lathes generally.

#### Cleaning

Use benzine to remove the slush compound from the finished surfaces of the lathe. Let this clean-up be thorough, and be sure to remove every particle of grit or dirt from all bearing surfaces. Carefully clean out all of the oil holes, so that no dirt will be carried into any journal with the oil. The sliding tumbler gear under the headstock and the slip gear on the lead screw should work easily. The cross slide guard or extension of the lower compound rest slide should be removed by running the slide to the centre of the carriage; the guard may then be lifted off, the dovetail surface of the bridge cleaned and oiled, and guard replaced.

#### Foundation

A good, solid foundation is essential to best results in accuracy, rigidity and smoothness of finished work. Money spent to secure a solid base is true economy. Be sure the foundation is thoroughly laid before the lathe is placed. Never bolt the legs to the floor. The holes in the legs are for the lag screws which secure the lathe to the skids when crating it for shipment.

#### Levelling

No lathe can do good work or accurate work if it is not levelled exactly. Use a level which is very sensitive and accurate. A carpenter's or similar level is utterly useless for levelling a lathe bed. First lay the level on the flat track lengthwise with the bed, that is parallel with the track, and carefully level the bed 'sthwise. Now place the level upon a straight edge which rests on the front and rear arms of the carriage, having the carriage close up to the headstock, and carefully level the bed by the head end leg. Move the carriage along the bed, letting it rest over each successive leg, and level the bed by that leg.

In preliminary levelling, leave the middle legs a trifle low rather than too high. Do not disturb the position of the level across the wings. Do not lean against the lathe. After having traversed the whole length of the bed as described, move the carriage again to the head end and repeat the operation to make sure that there is no wind. Grouting may, if desired, then be run under and around, but not over, the feet. No bed, no matter how strong, is stiff enough to prevent springing out of line when set on an uneven base; and in such

a condition it is impossible to face or turn straight; hence the levelling of the bed is of the utmost importance to obtain smooth and accurate work.

#### Oiling

Ample and proper lubrication is essential to secure good results and preserve the bearings. It is false economy to use any but the best mineral oil, rich enough to lubricate the bearings, and with body enough to last a reasonable length of time, and with a 20 degrees cold test. Animal oil has a tendency to gum and clog the oil tubes in cold weather. Each lathe is thoroughly oiled before leaving the shop, but, after being cleaned and set up, all the bearings should be flooded with oil during the first few weeks of operation. The oil reservoirs on the spindle bearings of the headstock hold sufficient oil for a day's run under ordinary conditions. Where oil holes are plugged with wood, the regular oil cover or oil cup will be found in packing box.

#### To Ensure Accurate Work

If your lathe should not bore straight, level it carefully with a good level as already described. This will entirely overcome the difficulty.

If your lathe should not face straight, it also is merely a matter of levelling.

If your lathe should not turn straight, use the same levelling operation and then carefully test to see that the centres line up exactly with each other. Remember that if a long piece is turned between centres without steady or follow rest support the work itself will spring away from the tool to some extent.

If your lathe should chatter, it might be due to any one of several causes:

Improper levelling; correct as above.  
All four feet not resting solidly on the floor or on wedges.

Work extending too far from chuck; change method of chucking or run outer end in steady rest.

Too great a distance between centres without support on slender shaft; use steady rest.

Inaccurately fitted chuck plate.

Bolts which hold chuck to chuck plate not tight.

End play in the spindle; adjust by means of the collar and nut on rear end of spindle.

Cross slide not fitting the bridge tightly; adjust gib.

Compound rest gib loose; adjust.

Cutting edge of tool below centre.

Dirt between one of the centres and its bushing.

Tool not securely clamped in tool post.

If using a tool holder, the set screw holding the inserted cutter should be tight.

Machine thrown out of balance—by addition of special chucking fixtures;

by being speeded too high on some classes of work.

If your lathe should cut a drunken thread, tighten the nut on the tailstock end of the lead screw, if that nut is too loose. On the other hand, do not make the nut too tight, as it would then be difficult for you to get the sliding tumbler knob into the holes when the lathe is running. The lead screw is always in tension whether you are chasing right-hand or left-hand threads, because the pull is against the outer end of the bearing in either case.

Should you have occasion to remove any of the gears from the reverse plate, be sure, when replacing them, that they are properly located by the dowel pins.

Never leave your lathe with the chuck wrench remaining in the chuck—some one else might start up the lathe.

## OUR 1916 IRON AND STEEL OUTPUT

OFFICIAL figures compiled by the American Iron & Steel Institute show that the production of pig iron in Canada in the first half of the current year was 40 per cent. ahead of production in the corresponding period of 1915, and 11 per cent. ahead of production in the last half of that year. At the rate of production in the first half of this year it is possible, if not likely, that the output for the full twelve months will exceed the high record established in 1913.

The total production of pig iron up to June 30 of this year was 507,750 tons and compares with 366,825 tons in the first half of 1915, 458,595 tons in the second half, and 1,015,118 tons for the full twelve months of the record breaking year of 1913.

Production of steel ingots and castings in Canada, according to the Institute, promises to break all records in 1916. Last year, production was very near the high record of 1,042,503 tons in 1913. The output in 1915 was 912,755 tons, compared with only 743,352 tons in 1914, an increase for the year of approximately 22 per cent.

The figures are interesting as official confirmation of the results achieved by the Canadian manufacturers in their effort to overtake an insistent demand, which has promised not only a market for all that can be produced, but a market at extremely attractive prices.

### Pig Iron

The following table shows the production of pig iron in grades in 1915 and 1916

	First Half 1915.	Second Half 1915.	First Half 1916.
Basic .....	292,556	367,813	388,387
Bessemer .....	5,238	8,476	12,575
Foundry, etc. ....	59,646	66,123	95,602
All other .....	9,355	6,183	11,186
Total gr. tons..	366,825	458,595	507,750

The output of pig iron, though larger in 1915 than in 1914, was still far below the record of 1912 and 1913. Production for 1915 amounted to 825,420 tons, compared with 705,972 tons in 1914 and the high record of 1,015,118 tons in 1913. Basic pig iron was the only grade showing larger output than in 1913 and 1912. The production of this grade of pig iron was 660,369 tons, compared with 558,524 tons in 1913 and 489,799 tons in 1912. Following table shows production of grades of pig iron from 1910 to 1915:

Years	Basic	Bessemer	Foundry	All Other	Total
1910 .....	365,000	221,494	143,986	9,440	740,210
1911 .....	413,303	186,274	130,324	34,467	824,368
1912 .....	489,709	228,742	134,208	129	912,878
1913 .....	558,524	227,062	225,231	3,701	1,015,118
1914 .....	331,456	184,053	174,346	16,117	705,972
1915 .....	660,369	13,714	125,769	25,568	825,420

### Steel Production

The following table shows steel production since 1910:

Year	Open-Hearth	Bessemer	Other Kinds	Total
1910 .....	542,354	199,570	....	741,924
1911 .....	601,074	189,797	....	790,871
1912 .....	645,062	207,569	400	853,031
1913 .....	768,663	273,391	449	1,042,503
1914 .....	556,910	186,158	284	743,352
1915 .....	884,736	22,521	5,498	912,755

Production of steel rails in 1915 was far below the production of any year since 1905. Since that year, excluding 1915, output of steel rails in the Dominion has averaged in excess of 364,000 tons a year, comparing with only 209,752 tons in 1915. As will be seen from the following table, other finished rolled forms of leading products have equalled or exceeded previous year's outputs:

Product	1912	1913	1914	1915
Rails .....	423,885	506,709	382,244	209,752
Struct. shapes and wire rods.	64,082	68,048	59,050	114,829
Plates & sheets, nail plate, merchant bars, tie-plate bars, etc.	373,257	392,340	218,125	328,737
Grand total, tons .....	861,224	967,097	659,519	653,318

### Miscellaneous

Production of wire nails in 1915 is estimated at 1,636,000 kegs of 100 pounds, as compared with 1,144,000 kegs in 1914, an increase of 492,000 kegs, or nearly 5,000,000 pounds. Output of cast iron pipe amounted to 53,700 net tons, as compared with 93,200 tons in 1914, a decrease of 39,500 tons.

## EVERY MAN TO HIS OWN TRADE.

By J. H. R.

THERE are very few men who have not, at some time, been placed in a position of humility, on finding they were forced to relinquish a task they had at first considered as very simple. It seems to be a trait of human nature to think we are capable of performing certain tasks, as well, if not better than the other fellow, who in many instances has spent several years

of his life in acquiring the necessary knowledge for the successful accomplishment of his allotted duties.

Some years ago, while working in a jobbing shop, I was turning the outside of a large cylinder, about 30 inches long. When noon hour arrived, there remained a portion of about one inch to complete the cylinder and as I would not be on hand in the afternoon, I disengaged the feed but left the tool in position, expecting to rough off the remainder in the morning. Upon my return I noticed that a portion about  $\frac{3}{8}$  inch long had been very roughly torn off. Upon making inquiries of one of the men, I learned that the office superintendent had endeavored to complete the job, with the above result. His effort proved very discouraging, for he finally left off and returned to the office. Under ordinary conditions, he might have achieved his purpose, but as this particular lathe was badly worn, it required careful handling for satisfactory results. To start a cut, it was necessary to take up all the slack in the apron gears before engaging the friction feed, and even then it would be some little time before the saddle would commence to move. As these conditions were not known to the "Supt.," he had tried several handles with no apparent result, finally trying to finish the cut by feeding with the hand wheel.

Another case of mistaken ability was that of a preacher, who anticipated, without much trouble, making a joint in a water pipe connection. Having obtained an ordinary flat faced union and a quantity of red lead from an engineer next door, he started in to do the "little" job. A few hours later, the engineer was called in for advice, to find the preacher covered from head to foot with red lead and perspiring freely in an effort to stop the joint from leaking. The engineer looked at the job, shut the water off, released the union with great difficulty, as the other had been using brute strength (pardon the expression) in trying to get a tight joint, inserted a rubber gasket, replaced the nut, and when the water was turned on, no leak was evident. The preacher thanked the engineer, but what was said before his appearance was not recorded.

There are 63 distinct varieties of canaries to be exhibited this year at the Canadian National Exhibition, 31 different breeds of rabbits and 24 cavies.

There will be 21 sections for field grain this year at the Canadian National Exhibition, five for grain in sheaves, and a similar number for grain in sacks.

# PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

## UNIFLOW ENGINES FOR DRIVING ROD MILLS.

THE merits of the uniform type of steam engine are gradually compelling a wider appreciation of its capabilities. In the struggle for efficiency in power production, attention has been chiefly centred on the steam economy of this engine with a consequent lack of appreciation in regard to its conspicuous ability in another direction, viz. overload efficiency.

Without detracting from its increased general efficiency, one of the most desirable features of the uniflow engine is its capacity for extreme overloads with a flat steam consumption curve, tests having shown that 200 per cent. load can be carried with an increase in steam consumption of only 10 per cent. Such a fact renders this type of engine well adapted for fluctuating loads with high peaks such as rolling mills and electric stations.

The first applications of this type of engine to rolling mill service in America have just been carried out by the Nordberg Manufacturing Company, Mil-

ped, the larger one to drive a 12 in. rod mill, and the smaller a 9 in. rod mill, which illustrates clearly the distinguish-

CROSS-SECTION OF UNIFLOW TYPE OF CYLINDER SHOWING CENTRALLY LOCATED EXHAUST PORTS.

the accompanying illustrations showing ing features of the design. Live steam the principle of operation and some of is supplied to the interior of the two

CYLINDER HEAD AND CYLINDER FOR 44-IN. DIA. BY 50-IN. STROKE UNIFLOW ENGINE.

END VIEW OF FRAME SHOWING REINFORCEMENTS ON FLANGE WHICH CONNECTS TO CYLINDER PARTS.

waukee, Wis., for the Youngstown Sheet & Tube Company, Youngstown, O. Two engines have been completed and ship-

the larger parts in course of construction.

The general design of the cylinders

cylinder heads, which are duplicates in regard to general arrangement of passages, valves, etc. The cylinder proper

ELEVATION OF UNIFLOW ENGINE FOR DRIVING ROD MILL.

is of plain tubular form having cast around its centre portion an annular passage, into which the exhaust steam

the piston on the return stroke will force the steam back into the steam space without damage. These valves are

Tangye type, with side crank and fly-wheel. Heavy duty requirements are met throughout the design, the general

BED OF 44-IN. DIA. BY 50-IN. STROKE UNIFLOW ENGINE BEING MACHINED.

from either end of the cylinder alternately escapes as the piston uncovers in turn a number of ports in the cylinder wall. The piston is of considerable length being not quite equal to the stroke, and is provided with rings at either end.

The steam admission valves are of the double beat poppet type, and are operated from a lay shaft by a releasing valve gear with spring dashpots, the cut-off being under control of the governor through the wide range of loads. As the only means of exhaust is through the ports referred to, the steam flows in one direction only, hence the name uniflow, consequently the ends of the cylinder are not cooled by the rush of exhausting steam which takes place at the point farthest from the ends. The temperature of the various parts, therefore, although it varies from the heads to the centre, is constant, and thereby renders the engine suited for a high ratio of expansion. Steam may be expanded from boiler pressure down to condenser pressure in one stroke, the steam economy of a single cylinder engine being equal to that of a modern compound engine.

Relief valves connect the interior of the cylinder with the live steam space

on the lower side of the heads, and are of the poppet type fitted with a cataraet dampening device. A feature of the valves is the absence of packing on the valve stems, which are accurately ground and lapped bushings.

The frame as will be observed from the illustrations, is of the horizontal

specifications and principal sizes of the two engines being as follows:—

so that should an excess amount of steam remain in the cylinder due to loss of vacuum from any cause, the pressure resulting from this being compressed by

### POLISHING LATHE WITH PUSH BUTTON CONTROL

THE adoption of push-button control and the provision of individual locking devices for each spindle are among the principal features of a new design of motor-driven polishing and buffing lathe developed by the Gardner Machine Co.,

the base at this end, and discharged downward through the other end, thus obtaining a circulation of air which prevents the motor overheating under normal conditions.

When direct current motors are used, an adjustable speed range is available, the desired speed being obtained by

FIG. 1—PORTABLE LIGHT AND ACETYLENE GENERATOR

Beloit, Wis. The control panel is arranged on the front of the machine as illustrated on page 183, the starting button on the right being sunk below the surface of the panel so as to eliminate any possibility of accidental starting. Further safety is provided by a simple device which locks the stopping button at the left of the panel.

The machine is built in several sizes, for either direct or alternating current, the motors used being fully enclosed so

moving a lever within the base. When using alternating current the speed adjustment is not so great as certain speeds only are available.

The spindles are locked, when changing wheels, by means of plunger pins mounted on the ends of the motor casing. These pins are normally held free by springs, and when in use are inserted into any one of four holes spaced around the collars seen in the photo, being lock-

FIG. 2—PORTABLE LIGHT AND ACETYLENE GENERATOR

as to be proof against dirt and dust. Internal cooling of the motor is provided by a fan on the shaft, inside of the right hand cover, air being drawn from

ed in position by thumbscrews while changing wheels. Ball bearings are used on the armature shaft, suitable end frames being used for this purpose.

### PORTABLE LIGHT AND ACETYLENE GENERATOR.

THE Garrow light recently put on the market by The Canadian Fairbanks-Morse Co., is designed to meet the requirements of contractors, miners, and others for a portable acetylene flare light of high candle power. This light is also suitable for use as a generator for cutting and welding by the oxy-acetylene process. The outfit consists of a Garrow Light, a tank of oxygen and a "low-pressure" welding or cutting torch. Fig. 1 shows several structural steel shapes that were cut in an average time of one minute and Fig. 2 shows the cutting up of a locomotive. The tire and main frame were cut in less than two minutes and the 7½ inch steel shaft shown between the light and the oxygen bottle was cut completely through in seven minutes. Welding may be done at proportional speeds, while an advantage of the outfit is that an 8000 candle power light is available at all times when the work is being done in dark or confined places.

The apparatus as illustrated weighs 70 lbs. and uses 9 lbs. of carbide at a charge. This provides 50 cu. ft. of

RUBBER AND STEEL VALVE.

acetylene gas at a cost of about ½ cent per cu. ft. The light can be recharged in two minutes, and has a patented by-pass that burns any excess gas produced, obviating all danger or smell of escaping gas.

### COMBINATION RUBBER AND STEEL VALVE.

THE use of a special process by which rubber is securely and lastingly attached to steel enables the makers of the Rub-Steel valve to produce a valve which resists warping and twisting under high pressures, and possesses the desirable seating qualities of a rubber surface.

The construction consists of a plate of high-grade steel placed in the centre of the valve with a tough rubber composition on each side and edge. Because of the rigidity of form thus obtained, the surface of the valve retains its true normal position, and is not forced through the grating by high pressure. Its reduced thickness gives greater efficiency to the pump, and when pumping hot water, a softer valve may be used, thus securing a better seat on worn or uneven grids.

These valves are manufactured exclusively by Voorhees Rubber Mfg. Co.,

Jersey City, in four different grades covering all ordinary conditions as well as extra high temperatures, and condenser service. Canadian Fairbanks-Morse are Dominion agents.

### SHELL BANDING PRESS

A SHELL banding press possessing interesting features of construction has been developed by Pullan & Mann, Leeds, Eng. The accompanying illustration shows the essential features of

SHELL BANDING PRESS.

the machine which is operated mechanically on the lines of an ordinary power press, with eccentric rod and crosshead. The eccentric shaft is carried in bearings cast integral with the main frame and is driven through heavy spur gearing from the pinion shaft which extends across the frame, one end carrying the tight and loose pulleys and the other a suitable flywheel.

The dies which compress the band are three in number, two being mounted on the base plate and the third being fastened to the crosshead, which is moved up and down by the eccentric rod and is guided by four tie rods as shown. At the upper ends of the tie rods are mounted four heavy coil springs which receive the upward thrust from the eccentric rod, the main frame being flexibly connected to the base plate to allow of a slight upward movement when the compression on the band reaches a maximum.

Spring tension is adjusted by lock nuts on top of the rods, while the position of the upper die at the lower end of stroke is adjusted by lock nuts on the outer pair of the rods below the eccentric shaft bearings. A belt shipper handle is provided at the left side of

the machine which delivers a number of blows on the band, the shell being turned around to distribute the pressure.

### CORE MAKING MACHINE FOR GENERAL WORK

THE core making machine shown in the accompanying illustration is capable of making cores from 1 in. to 14 in. long, and will fill boxes using 200 cu. in. of sand. The sand is supplied by an elevating and feeding device by means of which the supply of sand is regulated to suit the core being made.

Compressed air is used for supplying the sand to the core boxes, which are filled at the rate of eight per minute regardless of the size of core in each box, the number of cores contained in any one box being limited by the size of box which the operator can handle at the speed of the machine. Surplus air escapes from the core immediately after the box is filled, leaving the core porous, firm, and strong. The presence of air in the sand when being compressed provides a natural vent for the gases to escape by when the casting is poured.

Cores may be made of sharp sand, loam sand or green sand, using any satisfactory binder except excessive flour. The air pressure required for sharp sand cores is from 80 to 90 lbs. per sq. in. and with loam sand, 100 to 115 lbs. per sq. in. The core box is automatically clamped in position to receive the charge of sand, as also the sealing of the ends and the clamping of the box together sidewise.

The mechanical operation of the machine requires about one horse-power, while approximately 12 cu. ft. of free air are necessary for the pneumatic operation. Its use is not confined to straight cores, but includes all general work of specialty manufacturers also.

The builders of this machine are Wm. Demmler & Bros., Kewanee, Ill.

### BIG INCREASE IN TRADE

AN increase of nearly half a billion in the total trade of Canada is indicated by preliminary trade figures covering the 12 months ending with May last which have been issued by the Trade and Commerce Department. The total was \$1,563,230,513.

As regards exports, the total this year was \$820,000,000 as against \$432,000,000 in 1915, and \$358,000,000 in 1913. The greatest increase is in the export of manufactured goods, which has risen from \$54,000,000 in 1915, to \$261,000,000. Agricultural produce rose from \$45,000,000 to \$107,000,000; mine products from \$57,000,000 to \$68,000,000, fisheries from \$16,000,000 to \$23,000,000, products of the forest from \$43,000,000 to \$52,000,000.

The greatest increase has been in exports to Great Britain, mostly of war supplies, the total being \$518,000,000, as compared with \$180,000,000. However, that this prosperity is not all war-produced is evident from the fact that exports to the United States also increased from \$167,000,000 to \$337,000,000. There was also an increase to France from \$3,000,000 to \$37,000,000.

There was a decrease in imports, those of dutiable goods dropping from \$447,000,000 the year before the war to \$321,000,000, the chief decrease being in imports from Great Britain, which fell off from \$143,000,000 before the war to \$86,000,000.

As early as 1882 a State deputation from Ohio visited the Canadian National Exhibition looking for pointers and they have been coming from various States ever since, many of the United States fairs being modelled along Toronto lines.

Legislation was once threatened to prevent Toronto holding an Exhibition except in years specified by the Ontario Government. Fortunately, the matter never reached the House.

### OUR MUNITIONS PRODUCTION SHORTAGE— WHY?

OFFICIAL intimation has been made that munitions production in Canada has developed an unhealthy tendency. In a word, the output of shell parts is away below what it should be, and therefore scheduled shipments of completed shells—large and small—are not being maintained. The unfortunate situation may be said to arise from a variety of causes, each contributing its quota, and all, of course, bearing towards the undesirable. Raw and semi-finished materials entering into the manufacture of shells, labor shortage, and prices current which Canadian manufacturers receive, constitute, we believe, the main directions in which to seek the remedy.

In the matter of steel, the contracts already placed and those awaiting disposal among our shell-forging and machining plants surpass the capacity of our steel mills to produce on schedule, with the result that we are more or less dependent on U.S. steel mills to make good the shortage. These, of course, as is well known are also taxed to capacity to meet not only the munitions demands of their own forging and machining plants and the direct requirements of the Allied Nations, but those of a domestic nature in addition. To say that fancy prices are being realized for munitions material by the steel mills is quite a mild way of expressing oneself.

#### Male and Female Labor Problems

Regarding labor shortage and possible labor inefficiency both may be said to be existent, and the former possessive of a tendency to still further acuteness. While recruiting for overseas service has denuded our metal-working plants of a large proportion of what may be termed their regular employees, it has at the same time made replacement and augmentation a problem of considerable magnitude, the double contingency appearing at a time when the opportunities for forging and machining plant capacity outputs are without parallel.

The introduction of female labor is being sought as the remedy, both with the idea of filling the places of men who have enlisted and of making possible in due time the enlistment of other eligible men. In a number of

plants this dilution of labor, as it is called, is already in practice, and not only are great things expected of it, but a tendency to something like rampant enthusiasm is abroad to foster it, especially by the executives of Women's Societies and Associations. A disposition is apparent as a result to find fault with and criticize our metal-working plant administrations for their caution, shall we say, in ushering in and developing the scheme. The place and part that women are taking in munitions manufacture in Great Britain are being given the necessary prominence by way of making the appeal to our plant managements of the greatest possible effect; unfortunately, however, for those making the appeal a limited knowledge of the circumstances there and here is at best available.

#### Plant Adaptation to Female Labor

There are, we believe, no Canadian manufacturers of munitions but would welcome the assistance of female labor. Their plants are, however, in the great majority of cases wholly unsuited for the purpose, and just here it should be noted that women munitions workers are most largely employed in Great Britain in specially designed and equipped national factories, the origin and establishment of which has been a wartime development. Canadian munitions manufacturers are face to face with the problem of erecting and equipping either wholly new plants or of making extensive and expensive additions to those already existing, and just to what length and under what circumstances they are prepared to commit themselves, brimful even of patriotism as they have proved themselves to be, outsiders may not judge.

As to our reference to labor inefficiency, such a condition has in some measure contributed to the falling off in output, particularly in the steel mill and forging departments. Here, however, perhaps extenuating circumstances may justly be pleaded, as more or less continuous tropical weather has been quite generally experienced in recent weeks. Under any weather circumstances, the men engaged in the departments indicated, no matter how exemplary the provision for their welfare, may be said to be highly susceptible to at least a temporary relaxation of effort.

#### Munitions Contract Prices

The prices current which Canadian manufacturers receive for shell parts, shell forgings, shell machining, etc., are, we believe, contributing quite as much as anything else to our diminished output. In the early days of shell-making in Canada, fabulous and extravagant prices were reckoned to have been paid our forging and machining plants. It looks as though we had now gone to the opposite extreme. Dissatisfaction exists, we understand, with the prices at which shell machining, shell forging, and shell part contracts are now being let, all the way down from the largest to the smallest, and so much so as to breed indifference regarding acceptance of orders. This war is to be won in our steel mills, in our forges and in our machine shops, and a price has got to be paid. The men who manage our plants are men of business and realize that as the successful conclusion of this war is now a business enterprise, it must needs be conducted according to the ethics of sound business. In a word, to do their part and sustain it to the bitter end, the prices paid must be commensurate with the manufacturing feature of the task.

Reverting to the employment of female labor in our metal-working plants, the solution is right up to the Imperial Munitions Board if Great Britain's achievement is to be emulated. The prices current for shells and shell parts for production in Canada are also due to receive the Board's immediate attention.

## INDUSTRIAL NOTABILITIES

**P**ERCY C. BROOKS, vice-president in charge of manufacturing, the Canadian Fairbanks-Morse Co., Toronto, was born at Memphis, Tenn., March 24th, 1872, the son of Edward W. and Eliza (Ralston) Brooks. He was educated at the Military Academy, the University of Georgia, and at the Georgia School of Technology. His engineering career began in 1892, and, six years later, in 1898, he became associated with the Fairbanks-Morse Co. as assistant to the president at Beloit, Wis. In 1906 he was appointed general manager at Toronto, and in 1910 was made vice-president of the Canadian enterprise.

PERCY C. BROOKS

Mr. Brooks married Edith King, daughter of Henry King, of New York City, on February 14, 1914, the family consisting of one daughter. His clubs are Lambton Golf, R.C.Y.C., Economics, Hartley Bay Hunting and Fishing; his societies, the A.F. & A.M., and his recreations, golf, fishing and shooting. In politics Mr. Brooks is Conservative and in religion a Presbyterian. His residence is Parkview Mansions, Toronto.

lets and bars are relatively heavy, and an apparent shortage for prompt delivery has developed, with a corresponding stiffening of the market. In some cases consumers are meeting the situation by using first class shell steel discards. Pittsburg quotations on open hearth steel have been advanced \$2 a ton. A similar advance has been, by some producers, placed on structural material. The situation in plates is becoming tighter and an advance of \$2 per ton went into effect on Aug. 4. Sheets are fairly active, the demand for blue annealed being good. Owing to the condition of the spelter market, it is expected that galvanized sheets will weaken, but no change has as yet developed. This is due to the fact that the recent collapse in spelter has not yet reached the sheet product; however, unless a firmer tone is soon shown declines are looked for. Even should spelter become stronger, some slight decline in galvanized sheets is not unlikely. Inquiries for wire and wire products show an improvement, an advance of \$2 being recently put into effect on the American market. Local dealers however, in the expectation of a stronger market are holding prices firm. The demand for boiler tubes, is taxing the capacity of many mills, bookings in some cases being as much as a year in advance. The local situation is unchanged, but dealers are expecting to revise some of their lists.

**Machine Tools and Supplies**

The general situation throughout the machine tool industry has shown little change. The activity recently developed by the demand for the larger tools, required for the manufacture of the heavier shells has apparently passed its maximum and indications point to a gradual decline from now on. However, a fair amount of business is still passing. Considerable interest is being shown in the domestic demand, which has grown to a very encouraging volume. The requirements of the trade still call for large quantities of machine tool accessories and supplies. The situation in this respect is however, not as tense as a few month ago, and delivery on all needed equipment is more prompt, in many instances prices are also easier.

No great change has taken place in the metal situation. Increased activity has given a better tone to copper. Tin is quiet and unsettled. Spelter is weaker in an indifferent market. Antimony continues dull, with prices easier.

**Copper.**—Increased activity is noted in the copper situation and higher prices are expected. Negotiations for large supplies of copper by the British Government have been concluded, and it is expected the quantity of metal under contract will be about 150,000 tons, delivery to extend throughout

## The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

**Montreal, Que., Aug. 14, 1916.**—The general trend of our industrial activity is much the same as a week ago. Production (in many lines) which was affected owing to the extreme heat of the past few weeks, is gradually assuming more normal conditions and outputs are regaining the standard being maintained immediately previous. It is however, not expected to reach its high point for some time yet, as the holiday season is still on. Encouraging reports continue to arrive of crop conditions in all parts of the country, and railroads have been active in making preparations to handle the grain and in securing the help necessary to harvest the same. The steel

situation is showing signs of improvement, and some lines are beginning to strengthen. Ship-building is active but handicapped for lack of steel plates and other necessary material.

**Steel**

The long period of steadiness, which has prevailed in steel for a couple of months, is showing signs of breaking, but in an upward direction. Indications point to a number of advances, the market undoubtedly gaining strength, and some lines already showing increases. There is no abatement in demand and the mills are still heavily taxed to meet requirements. Foreign inquiries for bil-

all next year. It is also certain that other Allied Governments have been buying heavy. The trend of the market with prospects of a further advance has created an additional demand from domestic consumers, the buying movement as a result being more general. The increase in the volume of war orders has necessitated manufacturers covering their copper requirements. The demands being made upon producers for early delivery are very heavy, and it is almost impossible for the refineries to fill orders for short period shipment. With the total disappearance of second-hand metal and the existing high pressure it is more than likely that quotations will show further advances. London reports a very strong market, with prices going up. Standard spot is quoted at £11 10s., being an advance of £5 10s. during the week. Futures have advanced a similar amount, and are quoted at £109 10s. Electro spot at £124 shows an advance of £1 per ton. New York market is active, with prices advancing. Prime lake is  $\frac{1}{2}$ c stronger, and is quoted at  $26\frac{1}{2}$ c; electrolytic is firm at 27c, but is expected to become stronger. Dealers here report a little increased activity, with prices holding firm at 31c for lake and electrolytic, and 30c for castings.

**Tin.**—The market at present is a little unsettled, due to increased difficulty in obtaining shipping permits. This is causing a little uneasiness among American buyers, and the tone of the market is a shade stronger. If excessive buying should develop it is anticipated that tin will advance. Prices on futures are hard to obtain, as sellers are dubious of quoting under present market figures. Recent advances on the London market denote a rising tendency, a £3 10s. advance on standard spot and futures, and £3 on Straits spot having placed the current

prices at £171, £172 and \$171.10s. respectively. New York reports an advance of .825 cents per pound, the quotation being 38½c. Dealers here report a steady market at last week's price of 43c per pound.

**Spelter.**—A revival in the foreign demand for spelter, which resulted in considerable buying, has placed the market in a somewhat unsettled condition, and domestic consumers are showing a little uneasiness as regards the situation.

Owing to the relapse recently experienced, both galvanized and brass in-

vance of £2 on spot and £1 on futures, the latest quotations being £49 and £43 respectively. New York, however, while apparently active, has declined to 8.675 cents, a drop of  $\frac{1}{8}$ c per pound. The local situation is unchanged, with prices firm at 14c per pound.

**Lead.**—The decline recently noted in the price of lead has not resulted in a very heavy demand, as was anticipated, although considerable buying has been reported. Consumers are under the impression that lead will be still lower. It is understood that while both the Trust and outside interests were nominally on the same basis, sales were made by the latter at a lower figure. It is, however, generally believed that the independents will again return to the basis of the Trust price. London reports a better demand and quotations show a slight advance—15 shillings on spot and 12 shillings on futures, or a basis of £29/5 £28/12½ respectively. The nominal price on the New York market remains firm at 6c. Local dealers are quoting 8¼c on a fairly steady market.

**Antimony.**—The market continues to weaken, despite the fact that buying has recently shown a little improvement. Holders of metal are apparently anxious to dispose of it even at a loss, as quite a number have considerable stock on hand, for which they paid almost double the price they can get for it now. New York quotations have again declined 2c, being quoted at 10¼c per pound. Dealers here are asking 15c on a very weak market, a decline of 1c per pound.

**Aluminum.**—The situation is unchanged, and prices are firm at 68c per pound.

#### Scrap

Few developments have taken place in the scrap situation. The strength being shown in the steel market is not yet re-

### CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion \$100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

terests have been fairly heavy buyers, and the requirements of the markets abroad, if heavy, may result in a stronger market, with a corresponding increase in price. Just what the exact position is at present is difficult to say, as the movement now on may prove to be of short duration, like that of a few weeks ago. It is safe to say that producers are not over-exerting themselves in stocking the market at present prices, as in some instances, small producers can make little or no profit under existing conditions. A slightly stronger market in London has resulted in an ad-

## Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

#### BRAZIL

Bahia, British Consul.  
Rio de Janeiro, British Consul General.

#### CHILE

Valparaiso, British Consul General.

#### COLOMBIA

Bagota, British Consul General.

#### ECUADOR

Quito, British Consul General.

#### EGYPT

Alexandria, British Consul General.

#### FRANCE

Havre, British Consul General.  
Marseilles, British Consul General.

#### INDIA

Calcutta, Director General of Commercial Intelligence.

#### ITALY

Genoa, British Consul General.  
Milan, British Consul.

#### MEXICO

Mexico, British Consul General.

#### NETHERLANDS

Amsterdam, British Consul.

#### PANAMA

Colon, British Consul.  
Panama, British Vice-Consul.

#### PERU

Lima, British Vice-Consul.

#### PORTUGAL

Lisbon, British Consul.

#### RUSSIA

Moscow, British Consul General.  
Petrograd, British Consul.  
Vladivostok, British Consul.  
Odessa, British Consul General.

#### SPAIN

Barcelona, British Consul General.  
Madrid, British Consul.

#### SWEDEN

Stockholm, British Consul.

#### SWITZERLAND

Geneva, British Consul.

#### URUGUAY

Monte Video, British Vice-Consul.

#### VENEZUELA

Caracas, British Vice-Consul.

fleeted in old materials, and, with the exception of steel axles, which have advanced  $1\frac{1}{2}c$  to a basis of  $14\frac{1}{2}c$  per pound, general quotations are reported by local dealers as steady. Old copper has advanced  $\frac{1}{2}c$  per pound, being now  $15\frac{1}{2}c$  for light copper and  $18\frac{1}{2}c$  for crucible, heavy and wire.

**Toronto, Ont., Aug. 17.**—The falling behind in the deliveries of munitions is the subject of a statement recently given out by the Imperial Munitions Board. The shortage of production is largely due to the inadequate supply of sufficiently skilled labor, which is adversely affecting not only the machine shops, but also forging plants and factories making component parts. It is absolutely essential that all those engaged in the manufacture of munitions should co-operate in order to secure an increased production of munitions. The shortage of labor is also hampering other industries. The situation in this regard is becoming acute, and no serious effort has so far been made to relieve it.

### Steel

Although easier conditions in the steel trade have been predicted, there is apparently little possibility of this taking place for some months, as there are now indications of considerable firmness in the market. This is evidenced by the recent advance in the States of \$2 per ton on steel bars and wire, and higher prices on billets. The increased strength in the market is further indicated by the big contract for shell steel, amounting to 500,000 tons, recently closed in the States by representatives of the Allies. No statement has been made, and perhaps will not be for some time to come, as to the extent Canadian mills will benefit by this new buying movement, but it is fair to presume that they will get as much business as they are able to take care of. Production of steel in Canada this year will no doubt beat all previous records, and will probably run into well over one million tons. What may be termed ordinary business has been exceptionally good so far this month, considering the time of the year and owing to the otherwise industrial activity. With renewed strength in the market, prices are considerably firmer, and indications point to still higher prices on some steel products. Steel and iron bars have already advanced 10¢ per 100 lbs., and it is fully expected that plates will be affected in the near future. Prices of boiler tubes are very firm. The demand in the primary market is very heavy and deliveries extend well over a year. Wrought iron pipe is also very firm, and the skelp situation is unchanged. Wire nails have advanced 10¢ per keg, and are now quoted at \$3.80 per keg base.

The sheet market continues irregular.

with prices firm and unchanged. The demand for blue annealed sheets in the primary market is unusually active, but black sheets are quiet. Sheet bars continue very firm, with the prospect of higher prices, while production has fallen off, due to the hot weather. The galvanized sheet market is unsettled, but quotations are unchanged.

The steel market in the United States is stronger, due to heavy export demand; domestic buying is light for the time being. The contract for shell steel which the Allies have placed in the States calls for 500,000 tons of material, and includes billets, rounds and forgings, delivery to be completed by the end of July, 1917. The prices range from \$40 to \$90 per ton, according to quality of the steel, making an average price of \$67.50 per ton. The market is very active, and the general opinion of producers is that another buying movement has started. Many domestic consumers are said to have not covered their requirements for steel on business booked, and shell steel, plates, bars, etc., are now being sought in large quantities. These orders must eventually be placed, which will tend to strengthen the market still further. The United States Steel Corporation reports unfilled tonnage on hand on July 31 at 9,593,592 tons, a decrease of 46,800 tons, as compared with 9,640,458 tons on June 30.

### Pig Iron

The situation in the pig iron market is unchanged, and the consumption of steel-making grades of iron continues exceptionally heavy. The production of pig iron in the first half of this year was 40 per cent. ahead of the production in the corresponding period of 1915, and 11 per cent. ahead of production in the last half of that year. It is predicted that the output for this year will exceed the high record of 1913.

### Scrap

The market continues dull, with little of interest to note. Prices remain steady and few changes of importance have been made. Heavy smelting steel is quiet, although the demand continues heavy. Copper and brass scrap are firm and unchanged, while quotations on both lead and zinc have a weaker tendency.

### Machine Tools

Interest continues to be centered on munition contracts, and a number of inquiries have been received recently by local machinery houses for tools for machining large shells. While business continues good, it is not as active as it was, the reason being, of course, that many munition plants are fully equipped. Orders being placed now are largely confined to heavy duty lathes.

### Supplies

Business continues brisk and prices steady but firm. Iron, steel and brass

supplies are particularly firm, and an advance in some lines is looked for. An advance has been made in some lines of hack saw blades; mounted grindstones have also advanced. Soldering coppers have declined 2¢ per pound. Linseed oil and turpentine are both unchanged and firm. Gasoline and benzine have declined 1¢ per gallon following three reductions in the States in the price of crude oil, making a total of 25¢ per barrel. Canadian crude has declined 5¢ per barrel.

### Metals

With the exception of copper, the metal markets generally have been dull and weak during the past week. Business is rather quiet, which may be expected at this season of the year. The undertone in the copper market is very strong, due to heavy demand for this metal for munitions. The demand for tin continues light and prices are receding. Spelter is also weak, with a small volume of business. Lead continues weak, with the outside market now lower than the Trust price. Antimony has declined again and the market continues weak, but aluminum is unchanged. Solders have declined following the reduction in prices of lead and tin.

**Copper.**—Quotations continue nominal, but the market is stronger on account of increased demand. It is reported that representatives of the Allies are negotiating for a large amount of copper with the leading U. S. producers for delivery over all of next year. There is practically no spot copper to be had, and much of the production to the end of the year has been disposed of. The market has a strong undertone and higher prices are not unlikely. Local quotations are unchanged and nominal at 29¢ per pound.

**Tin.**—Although the market is higher in London, quotations in New York are unchanged; the market, however, is weak. Large sellers are not pressing metal on the market, while consumers are not displaying much interest in tin. Local quotations are lower at 43¢ per pound.

**Spelter.**—The market continues weak, with light demand. Galvanizing interests have been buying fairly freely. Spelter has declined locally, and is now quoted at  $12\frac{1}{2}$ ¢ per pound.

**Lead.**—Business has been quiet, notwithstanding the recent reduction in price by the Trust to 6¢, New York. The outside market is a shade lower, but there is some possibility of a reaction. Lead quotations are unchanged at  $6\frac{1}{4}$ ¢ per pound.

**Antimony.**—Prices are still nominal, and the market continues weak. Antimony has declined 3¢ locally, and is now quoted at 16¢ per pound.

**Aluminum.**—The market is quiet but

firm, with quotations unchanged at 68c per pound.

**Solders.**—Quotations have declined 1c per lb. following the lower prices on lead and tin. Guaranteed is quoted at 27½¢ and strictly at 25½¢ per pound.

### LACHINE CANAL TRAFFIC IN JULY

ALTHOUGH the ten days that the Lachine Canal was practically closed to navigation and the water-borne stream of freight entering and issuing from Montreal, thereby interrupted, the totals for the month of July are nevertheless interesting in that they show certain changes in the tendencies of trade. For example, the 1,589,432 bushels of wheat brought down through the canal during last month only lack 283,235 bushels of reaching the total for July in 1915, and this is the more noticeable in that so far this year the monthly totals have been almost half of those for 1915. If there had been no hiatus in the daily receipts, it is believed that July's total this year would have exceeded the same month in 1915 very decidedly.

### Grain, Produce, Coal

The total grain received last month was 3,381,363 bushels, an increase of 122,503 bushels. The delay caused by the trouble in the Lachine Canal will show its effect more in August than in July as the boats which were delayed did discharge their cargoes in July, but they will be later in their next return trip. In addition to wheat the only grain to show a decrease for July was barley, 306,196 bushels having come down the canal, as against 391,906 bushels for the same month a year ago. Other grains showed increases as follows: Corn, 340,853 bushels, against nothing for July, 1915; oats, 948,152 bushels, an increase of 66,730; rye, 81,000, an increase of 57,865 bushels; and flaxseed, 49,000 bushels, an increase of 26,000.

For the whole season to date, however, 1916 falls 8,992,839 bushels short of 1915 in the total amount of grain brought down, the figures being 11,920,617 bushels and 20,913,456 bushels.

In produce the only increase shown is in the total of 1,073 packages of butter, as against 1,049 for July, 1915. Other statistics in this department for last

month are as follows: Flour, no sacks, as compared with 1,400 a year ago; eggs, 1,785 cases, 485 cases less than in July, 1915; cheese, 42,097 boxes, a decrease of 1,247 boxes.

Coal still maintains its lead, the 220,042 tons brought down last month being 34,427 tons in excess of the figures a year before last month.

### Vessel Trips and Passengers Carried

Other statistics of interest follow for the months of July in 1915 and 1916 respectively: Trips, 1,143 and 1,094, decrease 49; tonnage operated, 593,509 and 582,015, decrease 11,494; passengers carried, 22,656 and 22,299, decrease 357; cargo tonnage, 452,033 and 471,061, increase 19,029; light trips, 379 and 357, decrease 22. When it is considered that the warm weather during the time the canal was closed was ideal for the Rapids trip, it is evident that last month showed up better for passengers than July in 1915 in spite of the slight decrease.

From 1858 until 1878 the Toronto Fair was held in the old Asylum grounds on King Street West.

## CANADIAN COMMERCIAL INTELLIGENCE SERVICE

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

# INDUSTRIAL <sup>A<sub>N</sub>D</sup> CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

## Engineering

**Brockville, Ont.**—The Canadian Bridge Motor Car Co., will build an addition to their plant here.

**Sherbrooke, Que.**—The Canadian Ingersoll-Rand Co., will build a large addition to their machine shop.

**Welland, Ont.**—The Canadian Steel Foundries, Ltd., will build a forge shop at their plant here to cost about \$6,000.

**Welland, Ont.**—The Electro Steel & Metals, Ltd., will build an extension to the foundry at a cost of about \$10,000.

**Brantford, Ont.**—Another important industry, the Dominion Steel Products Co., is now practically assured for Brantford. The City Council, at a special meeting on Aug. 10, granted the company a fixed assessment of \$10,000, to run fourteen years. They will locate in Holmedale, where options have been secured on suitable available property. The Company propose erecting a factory to cost about \$50,000.

## Municipal

**Lyal, Man.**—The Town Council will construct an electric light and power plant at a cost of \$8,000.

**London, Ont.**—The City Council will call tenders for a number of pumping units for the waterworks system.

**St. Mary's, Ont.**—The Town Council are considering the advisability of installing a septic tank sewage disposal system at a cost of \$15,000.

**London, Ont.**—The City Council are considering the installation of a water wheel, electrical generator and 250-h.p. pump for the waterworks. Estimated cost, \$15,000. General Manager, E. V. Buchanan.

**Toronto, Ont.**—The York Township Council contemplate extensions to the water distribution system. The engineer Frank Barber has been instructed to prepare plans for 24 in. and 12 in. water mains.

**Watford, Ont.**—A bylaw to issue \$10,000 in debentures to pay for the installation of a hydro system here carried almost unanimously on Aug. 1. Construction of a line will be commenced at once.

**Hamilton, Ont.**—The City Council has voted in favor of improving the waterworks system and will send a special delegation to other cities with a view to ascertaining the best means of accomplishing this end.

**Hamilton, Ont.**—The recommendation of the Works Committee that a 20-in. water main be constructed on Main Street at a cost of \$11,468, has been adopted and the Board of Control instructed to purchase the necessary right-of-way.

**Hamilton, Ont.**—A gas expert at a cost not to exceed \$3,000 will be engaged to come here and go over the gas fields from which Hamilton's supply is obtained and report on the possibility of a supply in the future, and on the advisability of increasing same by the addition of coke gas.

## General Industrial

**Sarnia, Ont.**—An American concern contemplate establishing a dye works here.

**Walkerton, Ont.**—The Canada Spool & Bobbin Co., is having plans prepared for an addition to its plant which will increase its capacity over 50 per cent.

## Trade Gossip

**The International Engineering Co.,** Amherst, N.S., have sold two 600 h.p. water tube boilers to the Goodyear Tire & Rubber Co. for their plant at New Toronto, Ont.

**Niagara Falls, Ont.**—Mrs. Thompson, wife of J. Enoch Thompson, Spanish Consul at Toronto, opened the aerial tramway over the Whirlpool, constructed by the Niagara Spanish Aero-car Co., on August 8.

**Canadian Vickers Co.**—The London Times understands arrangements are being made for an issue of a million pounds sterling 6 per cent. debentures on behalf of Canadian Vickers Co. It is believed the issue will be redeemable by a sinking fund during a period of twenty years.

**Business for Canada.**—It is reported from London, England that Canadian Trade Commission which has been conducting a campaign in the interests of

Canadian business, has carried out its mission most successfully. It was announced to-day that 1,700 forms have been filled in by British manufacturers and merchants who pledged themselves to purchase from and sell to Canadian houses the goods which were formerly purchased from and sold to enemy countries.

**Ontario Steel Products.**—The retiring board of directors of Ontario Steel Products was re-elected at the annual meeting, held recently at Gananoque, Ont. The board is as follows:—W. Wallace Jones, Toronto; Dr. N. C. Jones, Toronto; J. T. Richardson, Toronto; W. T. Sampson, Gananoque; D. Ford Jones, Gananoque; F. P. Jones, Montreal; F. Bacon, Montreal; Kenneth Nelson, Montreal; W. M. Byers, Gananoque. The officers are—President, W. Wallace Jones; vice-president and general manager, W. T. Sampson; secretary-treasurer, F. Petch.

**Huge Steel Contracts.**—It is reported from New York that contracts calling for 500,000 tons of shell steel, and valued at \$34,000,000 were closed on August 11, between representatives of the Allies and the United States Steel Corporation, acting with several large independent companies. This business is the largest steel contract placed since the war began. The order includes semi-finished (billets), rounds and forgings, and delivery is to be completed by the end of July, 1917. The material will be used abroad in the manufacture of high explosive shells.

**Oil-bearing Shales.**—A proposal has been submitted to the Dominion Government asking that it encourage the development of the oil-bearing shales, of which there are known to be large deposits in New Brunswick, in parts of Saskatchewan and Alberta, and to some extent also in British Columbia. These shales exist not only in commercial quantities, but the resources are so rich as to provide for a considerable part of Canadian requirements, according to Louis Simpson, of Ottawa, who has made an exhaustive study of the subject. It is hoped by this means to reduce the price of gasoline.

**Big Copper Purchase.**—It is reported from New York that manufacturers supplying the Allies with munitions are negotiating for the largest copper purchase ever made in the United States. The amount required will be 250 million

## 28-in. Conradson Band Turning Engine Lathe

Strength. See the manner in which the head stock is cast integral with the bed? Compare that with the usual bolted construction. Two massive bronze worm

wheels are mounted on the spindle, driven by hardened worms with ball thrust bearings, the worms are driven by a train of heat-treated nickel schrome steel gears running in oil. The spindle thrust is taken by a massive ball thrust. The phosphor bronze bearings are of the conical sleeve type. Every feature is suggestive of strength. A look at the machine would convince you that it is strong.

**THE A. R. WILLIAMS**

**MACHINERY CO., LTD.**

## WE ARE NOT GOING TO GIVE YOU UP

We have a Geometric Self-Opening and Adjustable Screw-Cutting Die Head for you, and we want you to have it.

The big manufacturers are using them, and the smaller manufacturers cannot afford to do their thread cutting without them.

Geometric Self-Opening Die Heads, that release the work when the required length is reached, are furnished for cutting from 1-16-inch diameter up to the largest requirement, of any pitch and form.

Can be arranged for use on any make of Screw Machine

Let us know the line of thread cutting you have to do, and we will send you full particulars of the Die Head.

**THE GEOMETRIC TOOL CO., New Haven, Conn., U.S.A.**

pounds—about 15 per cent. of the country's entire prospective output for 1917. At present prices \$70,000,000 will be involved. The agreement on prices is the only detail that is holding up the order. One of the principals in the deal is away from the city, and when he returns the order will be completed at once. This, it is expected, will be in about three weeks.

**C.P.R. Tunnel Named.**—At the request of Lord Shaughnessy, His Royal Highness the Duke of Connaught, Governor-General of Canada, has graciously allowed the tunnel, which the Canadian Pacific Railway bored under the Selkirk Mountains, to be named after him. The Connaught Tunnel, which is five miles long, double-tracked, gives the Canadian Pacific Railway the lowest grade of any transcontinental line through the Selkirks. His Royal Highness went through this tunnel on 17th July last, when the bore had been completed. This tunnel was bored in less than three years, and therefore, holds the world's record for tunneling. The permanent tracks are now being laid in the tunnel, and trains will be running through it very shortly.

**C.P.R. Station Opened in Quebec.**—At Quebec on August 10, the new C.P.R. station, the Palais, was opened under most auspicious circumstances. Nearly all Quebec turned out to witness the ceremony, and 250 specially invited guests were present at the luncheon provided in the new waiting room, which was artistically decorated for the occasion. A. D. MacTier, general manager of the Canadian Pacific, presided, and among those present were Major Lavigne and Madame Lavigne, Hon. T. Chase Casgrain, Hon. L. A. Taschereau, Minister of Public Works; Hon. N. Perodeau, M.L.C., and D. O. Lesperance chairman of the Quebec Harbor Commission, Dr. Reid, Minister of Customs and Acting Minister of Railways; Madame Casgrain, Sir Lomer Gouin, Premier of Quebec; Hon. J. S. Kaine, Hon. Geo. McCorkill, and F. L. Wanklyn, executive assistant of the C.P.R., etc.

## Tenders

**Carberry, Man.**—Tenders will be received up to August 25, for the purchase of the following oil tanks and outfits: Two complete steel oil tanks, capacity 12,000 American gallons each with two pumps, piping, fittings and all connections. Apply W. D. Card.

**Toronto, Ont.**—Tenders for extension to Duncan Street sub-station, and addressed to Chairman, Toronto Electric Commissioners, will be received until August 30. Plans, specifications and

form of tender may be obtained at the engineering offices, corner Dunearn and Nelson Streets.

**Ottawa, Ont.**—Tenders for Incandescent Lamps, Public Buildings, Ottawa, Ont., will be received August 22. Specifications to be seen on application to Thos. A. Hastings, Clerk of Works, Postal Station "F," Toronto; to R. L. Deschamps, Overseer, Dom. Bldgs., Montreal, and to the Chief Architect, Department of Public Works, Ottawa.

**Winnipeg, Man.**—Tenders will be received until August 21 for the various works required in the completion of the New Parliament Buildings, and not included in the general contract. The words include structural steel, heating and ventilation, electrical conduit and wiring. Particulars may be obtained from S. C. Oxtun, Deputy Minister of Public Works, Winnipeg.

**Ottawa, Ont.**—Tenders will be received until August 18, 1916, for the supply of filing cabinets for Dominion public buildings generally. Plans, specifications and forms of contract can be seen and forms of tender obtained on application to the office of Edwin Francis, caretaker, Post Office, London, Ont.; R. L. Deschamps, overseer of Dominion Buildings, Post Office, Montreal; Thos. A. Hastings, clerk of works, Postal Station "F," Toronto, and at the Department of Public Works, Ottawa.

**Tweed, Ont.**—Tenders will be received by the secretary-treasurer, High School Board, up to August 30, in whole or part, for the erection and completion of a high school building. Plans and specifications can be seen and all particulars procured at the architects' or secretary's offices. Ellis & Ellis, architects, Manning Chambers, Toronto; C. W. Huyek, secretary-treasurer, High School Board, Tweed.

**Ottawa, Ont.**—Tenders will be received up to August 24, for the construction of a reinforced concrete grain elevator with a capacity of 1,000,000 bushels. Plans, specifications and blank form of contract may be seen at the offices of the following: Chief Engineer, Department of Railways and Canals, Ottawa. Chief Engineer, Canadian Government Railways, Moncton Government Railways, Moncton, N.B. General Superintendent, Winnipeg, Man. Resident Engineer, Port William, Ont. John S. Metcalf Co., Engineers, Montreal, Que. Contractors who wish to obtain plans and specifications temporarily for their own use, may obtain same from any of the offices at which plans are on exhibition, on depositing a certified bank cheque in favor of the Canadian Government Railways for which will be refunded on the return of the plans and specifications.

## Personal

**C. T. Wimwood**, who died at the home of relatives at Big Point, near Chatham, Ont., was a prominent mining engineer and mining operator. He was president of the Bisbee Copper & Development Co.

**Sir George E. Foster**, Minister of Trade and Commerce, sailed for Canada last Friday, on the steamer Missanabie. Previous to going on board Sir George delivered an address before the members of the Liverpool Chamber of Commerce.

**Geo. A. Walkem**, managing director of the Vancouver Machinery Depot, who recently left for England with the object of joining his Majesty's forces, has obtained a commission in the Royal Engineers, and has left for Egypt, where he will be stationed for the present.

**William Yellowley**, superintendent of the Canadian Locomotive Works, Kingston, Ont., died at his home on August 6 of heart failure, aged 57. He was a native of Newcastle, England, and had been with the locomotive works for over 15 years. Deceased was a clever inventor, and had put into operation a number of time and labor-saving devices. He devised two machines, which have materially increased the output of shells. Both are widely used in Canada, the United States and England.

## Marine

**Vancouver, B.C.**—The Wallace Shipyard No. 1 is busy making preparations for the construction of a steel steamer for the Kishimoto Steamship Co., of Osaka, Japan.

**Victoria, B.C.**—The keel of the first of the three ships under construction by the Cameron-Genoa Mills Shipbuilders, was laid down at the new plant on July 29. The keel is 225 feet in length over all.

**Montreal, Que.**—The work of strengthening by steel piles the coffer dam which has been built at the break in the weir waste of the Lachine Canal is progressing favorably and traffic has been resumed.

**Vancouver, B.C.**—A. Wallace, head of the Wallace Shipyards, states that the contracts had been signed for the construction of three more auxiliary schooners for the H. W. Brown Co. This makes six schooners to be built at the Wallace Yard No. 2.

**The Vancouver Dredging & Salvage Co.**, have succeeded in floating the Japanese steamer Kenkon Maru, No. 3, which ran ashore near Mayne Island on January 12. The vessel has been placed

# Aikenhead's DUMORE GRINDER

The DUMORE Portable Grinder. The only small grinder giving wheels the correct surface speed. Speed, 30,000 R. P. M.

**Weights only 17 pounds**

**Can be set up in a moment in any Lathe, Shaper or Milling Machine**

**Does all kinds of Grinding and does each kind right :: :: :: :: ::**

**The Maclean Publishing Co., Limited**  
143-153 University Avenue, Toronto, Ontario

## WHITING AIR HOISTS

Most convenient for the many quick, short lifts about the average shop.

Valve stem does not pass through air chamber and therefore no packings are required.

Automatic cutoff guards against waste of air.

All details the result of many years' study in manufacturing and operating cranes and hoists of all kinds.

**Send for catalog 119.**

**Complete Foundry Equipments. Cranes of all Types.**

1719

*If any advertisement interests you, tear it out now and place with letters to be answered.*

## Stampings and Metal Specialties

We have the plant and equipment for turning out stampings of the highest quality in brass, copper, aluminum, tin and steel, and are prepared to undertake the manufacture of metal specialties of any description.

**PUNCHES, DIES,  
TOOLS.**

**COLEMAN FARE BOX  
COMPANY, LTD.**  
70 Bond St., Toronto

## The Metals Coating Co. of Canada, Ltd.

Versailles Building, 90 James St.  
**MONTREAL, CANADA**

A machine gun making its ammunition from Reeled Wire, and coating objects by bombarding with minute plastic particles of metal. The **Schoop method** of Metallic deposition, any object and any size coated with a positive adhesive and homogeneous coating with any metal for any desired thickness.

Solves one of the greatest problems heretofore confronting the structural engineer, because it produces on iron or steel a permanent coating not susceptible to corrosion.

Carbons can be coated with copper, etc.

For full information write for booklet "D".

in drydock at Esquimalt, B. C., and will be repaired by the Victoria Machine Depot.

**The Canada Steamship Lines'** steamer "Moreland" is being rebuilt at Duluth, Mich. The Morland was wrecked in 1912 on Saw Tooth Reef, Lake Superior, and her stern, the only portion left intact, is being fitted to a new forward part, which will make the new steamer over 600 feet in length.

**Chatham, N.B.**—The trial trip of the new pilot motor schooner, Admiral Beatty, built at the Miramichi Foundry Shipyard, was held recently. The boat is 72 feet over all, has a beam of 18 ft. 4 in., and a depth of 7 ft. 6 in. She has a 50 h.p. Regal gasoline engine, and is equipped with the regular rigging of a vessel of her class. Accommodation is provided for a crew of 14 men.

**Owen Sound, Ont.**—The Provincial Government has purchased the small steamer Wawana and is having her converted into a motor boat with oil engines. A complete reconstruction of her deck houses is being made to afford accommodation for the officers and crew. It is expected that the power installed will make the boat the speediest craft in the lake service.

**Lake Carriers' Advance Wages.**—At a meeting of the directors of the Lake Carriers' Association in Cleveland, Ohio, on August 2, wages were marked up \$10 a month for all men on boats below the grade of licensed officers, making a second general advance by the Association this season. An advance of 10 per cent. was made the men at the opening of the season. This action affects fully 10,000 men on the Great Lakes. The scale which was adopted is independent of the fall schedule effective in October.

**A. B. MacKay** of Hamilton, Ont., a well-known figure in lake shipping, has just purchased from the National Steamship Co., of Toronto, the steamer Natironeco at a price not disclosed. The Natironeco is a steel vessel of about 1,600 tons dead weight capacity. She was built at Detroit in 1892, and was transferred to Canadian registry about four years ago. At present she is engaged in carrying grain and coal on the upper lakes.

**Soo Canals Traffic.**—Records of traffic through St. Mary's Canals were broken in July, when 14,048,404 tons of freight were carried, an increase over the previous record made in June of 1,087,935 tons; 254 more vessel passages were made, compared with July of last year. Shipments of grain showed greatest increases. In 1915 there were 2,398,662 bushels of grain, and 3,938,366 bushels of wheat. During July this year 13,349,113 bushels of grain and 31,907,803

bushels of wheat went through. Iron ore also shows increase of 2,547,023 tons over July, 1916. Of the total amount of freight, 2,629,439 tons passed through the Canadian canal, and the balance of 11,418,965 tons through the American.

**Ottawa River Vessel Burned.**—The pleasure steamer G. B. Greene, owned by the Upper Ottawa Improvement Co., which has plied the waters of the Upper Ottawa River for over a quarter of a century, was burned to the water's edge off her berth at Quyon on the morning of July 27. Four members of the crew, who were trapped below decks when the fire broke out, lost their lives. They are: John Stevenson, fireman, Luskville, Que.; Alcide Guertin, deckhand, Aylmer, Que.; Oscar Lapierre, deckhand, Quyon, and George C. Bryant, first mate, Mattawa. Owing to the age of the vessel, the fire spread so rapidly that no attempt could be made to stay its progress, and the members of the crew, ten in number, barely escaped with their lives by jumping overboard and swimming ashore. The fire was first noticed about 1.30 by one of the deckhands, A. Gibson, who awoke to find the cabin full of smoke. He at once gave the alarm and rushing on deck found the amidships part of the vessel a mass of flames, which had burned the hawseers holding her to the wharf. The boat was drifting out into the stream, with flames shooting from every part of her. So quickly did the fire spread through the ancient timbers that the crew, hurriedly awakened out of their slumbers, had to dash through a barrier of flames and smoke to the deck.

**"Charles S. Price" Salvage.**—Salvage work on the sunken steamer Charles S. Price, known as the "mystery ship," was abandoned on July 25, by the Great Lakes Towing & Wrecking Co. Captain Cunning, wrecking master in charge, left for Cleveland, where he will make a detailed report to the underwriters. It is now probable that unless some wrecker cares to take a chance on blowing up the Price for the junk that is in her the boat is on the bottom for all time to come. In a statement made just before leaving Capt. Cunning said:—"We have abandoned the work entirely on the Price. There is nothing but a scrap heap there, and during the two working days that divers have explored the hull we have become convinced that it would be impossible to float the hull without spending a fortune, and there would be nothing to show for the work but a pile of junk. The interior of the steamer, in the boiler and engine rooms, indicates that the boilers exploded. I do not say this is true, but it is probable, as the aft bulkhead is shoved forward and the machinery is wrecked and pushed to-

# JAMES McKAY COMPANY

## Canadian National Exhibition

**Aug. 26—TORONTO—Sept. 11**

**“A little bigger; a little better.”**

**Federation of the Empire. 1,200 Performers. 400 Musicians.**

Gorgeous spectacle, symbolizing and epitomizing Imperial solidarity, power and cohesion. Mammoth scenic reproduction of British Houses of Parliament, Westminster Abbey and the War Office.

**WAR—on land, in the air, on and under sea.**

Scenes that have thrilled the world, re-enacted by Overseas troops. Model camp; trench warfare.

Anmer, the King's horse. Acres of manufactures. Glorious agricultural exhibits. Government exhibits and practical farm demonstrations.

*If any advertisement interests you, tear it out now and place with letters to be answered.*

wards the stern, indicating that an explosion or some other powerful agency tore everything to pieces. The aft section of the steamer is so badly damaged that repairs cannot be made under water. Our idea was to float the boat by compressed air, but with bulkheads broken and aft section damaged beyond repair, the air could not be controlled, and there was no chance. The aft and forward cabin sections are flat and part of the machinery is resting on the lake bottom. No bodies were found anywhere inside the hull, and if there are any in the vicinity they are so tangled up in the wreckage they never will be found."

## "PURO - FY"

(MADE IN CANADA)

THE American Museum of Safety conferred a Gold Medal Award upon the Puro Sanitary Drinking Fountain at the First International Exposition of Safety and Sanitation.

**Safe**  
**SANITARY**  
**Simple**  
**Economical**  
**Quickly Attached**

These are the qualities that forced the leading safety and sanitary engineers to pick Puro in preference to all others.

No device can be as efficient that does not contain all these qualifications; and Puro was not tied for first place. Puro was first.

Don't be satisfied with half-way goodness, or makeshift drinking arrangements for your employees.

If the men in your factory must drink, give them a clean drink.

Puro is clean—it does not rust or corrode.

Puro is economical. It allows just the proper amount of cool, clean, fresh water to come through the bubbler. No spurring, no overflowing, no loss. Puro regulates itself. You can attach it in five minutes.

Tell us how many men in your factory and your water pressure in pounds—

We'll tell you just what it will cost to "PURO-FY" YOUR WATER SUPPLY.

TRADE MARK

147 University Ave. TORONTO, ONT.

## Railways—Bridges

**London, Ont.**—Traffic on the London & Port Stanley Railway has increased to such an extent that the Commission is preparing data so as to submit a by-law next January to secure money for double-tracking and increased equipment.

**Brantford, Ont.**—The building permit for the new Lake Erie & Northern station was issued here last Friday, subject to the carrying out of the award of the Dominion Railway Board in regard to the transfer of certain lands. Work on the foundation has started and the new station, which will be a handsome one, will cost \$25,000. Schultz Bros. have the contract.

## Contracts Awarded

**Stratford, Ont.**—The City Council have awarded the contract for construction of a steel water tower to the Chicago Bridge & Iron Works, Chicago. Approximate cost, \$23,000.

**The H. G. Vogel Co., of Canada, Montreal,** has been awarded a contract for the installation of a sprinkler system at the Goodyear Tire & Rubber Co., plant at New Toronto, Ont.

**Prince Rupert, B.C.**—The City Council has let the following contracts for supplies required in connection with the new waterworks and power plant: Machinery, Canadian Fairbanks-Morse Co.; wood pipe, Vancouver Wood Pipe & Tank Co.; steel pipe, hydrants, etc., Campbell, Gordon & Co., Vancouver; pipe fittings, etc., Letson & Burpee, Vancouver.

## New Incorporations

**The Milton Foundry** has been incorporated at Toronto, with a capital of \$40,000, to carry on a foundry business at Milton, Ont. Incorporators: A. Fasken, Duncan McArthur, and E. H. Brower, all of Toronto.

**Feldspar & Clay Products** has been incorporated at Toronto, with a capital of \$1,500,000, to develop mining properties and treat ores and minerals of all kinds at Warton, Ont. Provisional directors are: T. M. Ferguson, J. P. Walsh and A. E. Kelly, all of Toronto.

## Refrigeration

**Galt, Ont.**—In order to produce revenue from surplus water from artesian wells in winter months and as a means of preserving the health of the com-

munity, the Galt Water Commission is considering going into the business of making artificial ice.

## Wood-Working

**Magog, Que.**—D. Audt's sawmill was recently destroyed by fire, the loss being estimated at \$8,000.

**Vancouver, B.C.**—The Alberta Lumber Co., has been granted a permit for the erection of a lumber mill to cost \$100,000.

Will  
Give You  
Exceptional

## Shell Forging Production

**WITHOUT AN EQUAL FOR BOTH FIRST AND SECOND OPERATION PUNCHES.**

Comes to you heat-treated and ready for use.

It does not stick to the work.

There are many cases where each punch has turned out over 2,000 shells.

It means more shells, per machine per day.

**STEEL OF EVERY DESCRIPTION.**

**Hawkridge Brothers Company**

303 Congress St., BOSTON, MASS. U.S.A.

**Toronto, Ont.**—The plant of Ewing & Murphy, wood turners, was completely destroyed by fire on July 25. According to an estimate made by Richard Ewing, senior partner of the firm, the loss entailed will be in the neighborhood of about \$10,000. The loss is partly covered by insurance.

## Catalogues

**The Roller-Smith Co.,** New York, has issued bulletin No. 200 illustrating and describing fully the "Roller-Smith" portable direct reading bond testers.

**Portable Ohmeters.**—Bulletin No. 300 recently issued by the Roller-Smith Co., New York, describes and illustrates the "Roller-Smith" portable direct reading slide wire ohmeter in two types, the telephone and galvanometer type.

**The American Pulley Co.,** Philadelphia, Pa., have issued a booklet entitled "Belt Pulleys" being a report of tests for belt slip. The booklet contains a description of testing apparatus, methods and results of test with five data sheets giving full particulars of the tests. There are also included a number of curves showing the slip for various types of pulleys.

**Tumblers.**—The Whiting Foundry Equipment Co., Harvey, Ill., have issued catalogue No. 120 illustrating and describing their line of tumblers and dust arresters for foundries. A brief specification is included covering the construction of the tumblers with detailed illustrations showing some of the parts, while the principal dimensions are given for the various sizes. Other lines dealt with include dry and wet cinder mills.

**Foundry Ladles.**—Catalogue No. 122, deals with a line of foundry ladles made by the Whiting Foundry Equipment Co., Harvey, Ill. The various types of crane ladles, crane truck and standard truck ladles, bottom tap ladles, etc., are illustrated and their principal features described. Tables are included giving the capacity and principal dimensions of the various sizes.

**The Brown Hoisting Machinery Co.,** Cleveland, Ohio, have issued a catalogue dealing with the "Brownhoist" suspended concrete coal bins for power plants. The construction of the bin is described fully and a number of views are included showing several large installations. Other illustrations show the "Brownhoist" weighing larry and locomotive cranes in operation in connection with the coal bins. A list is included of some plants where bins have been installed.

Steel Shell Forgings or Billets of any size or weight will move any distance or about curves upon our specially constructed Gravity Carriers and Incline or Horizontal power devices. No labor required.

**Canadian Mathews Gravity Carrier Co., Toronto**

## A Salesman Always on the Job

IT is the constant dropping that wears the stone away. It is the constant knocking at the door of attention and favor that in the end gives you ready access to the good-will of buyers of your merchandise.

You can keep up a constant knocking—a bid for attention, a reminder of yourself, a spokesman of your message—this by using regularly

## The FARMER'S MAGAZINE

No man whose customers and should-be customers are farmers should be absent from their attention. Their will and purpose to buy may mature at any time. The salesman on the spot stands the best chance to get the order.

All this you know, but—do you live up to the behest of your knowledge?

Let us tell you more about The Farmer's Magazine in a special letter.

*N.B.—Objectionable advertising not accepted. Both editorial and advertising columns are closely censored to keep them clean and decent.*

## KEYSEATER

for Milling Internal Keyseats

This tool is an attachment for the drilling machine, and is regularly made with straight shank for gripping in the drill chuck; taper shank can be had if desired. The tool is fitted with a high-speed steel rotary cutter for milling internal keyseats in one cut. To complete a keyseat it is only required to pass the tool through the hole just once. Innumerable inexpensive eccentric bushings are supplied whereby the tool may be bushed to meet any diameter above its own.

Write for Catalog C for full detail.  
**NATIONAL MACHINE TOOL CO.**  
2270-2272 Spring Grove Avenue,  
Cincinnati, Ohio, U.S.A.

Agents: The Canadian Fairbanks-Morse Co., Ltd., Montreal, St. John, Toronto, Winnipeg, Calgary, Vancouver, Ottawa, Quebec, Hamilton, Saskatoon and Victoria.

**Write us for prices.**

**Belt Pulleys** by Charles A. Brinley. A reprint of a paper recently read before the Engineer's Club of Philadelphia and issued by the American Pulley Co., Philadelphia, Pa. The intention of the paper was to draw the attention of engineers to the question of pulleys for the transmission of power by belts, and to point out that there is more in the selection of pulleys of a proper type than has been commonly supposed. The conclusions were arrived at by means of a number of tests, particulars and results being given accompanied by charts showing the respective merits of various types of pulleys. A list of data sheets is included to which references are made in the text, and this list can be obtained along with the reprint upon application to the American Pulley Co.

**The Vulcan Soot Cleaner Co., Du Bois, Pa.,** have recently published an attractive book dealing with the "Vulcan" soot cleaner as applied to boilers, superheaters, economizers, garbage destructor boilers, waste heat boilers and similar apparatus. The book is arranged in seven sections. Section 1.—"What Soot Really Is" points out the predominance of ash in most soot, and what happens if this is allowed to accumulate, not only as to reduction in efficiency, but by reason of the fusing and hardening of the deposit. Section 2.—"Why Clean Heating Surface Pays" gives the results of a large number of tests and investigations on the effect of soot deposit on efficiency of heating surface in boilers, superheaters and economizers, etc. Section 3.—"How Soot Cleaning Can Be Accomplished." Discusses the fundamental requirements of soot cleaning and what can be accomplished with hand-blowing. This is followed by a discussion of mechanical soot cleaning, which includes the principles of design of steam nozzles and their location in the boiler. Section 4.—Takes up the design of the "Vulcan" soot cleaner as applied to different types of water tube boilers. Section 5.—Is devoted to the "Vulcan" soot cleaner as applied to different types of fire-tube boilers. Section 6.—Is devoted to the application of "Vulcan" soot cleaners to economizers illustrating the design for both the straight and staggered tube types of economizer. Section 7.—"Details of Construction of the Vulcan Soot Cleaner," discusses the design of nozzles, anti-corrosion air relief valves and automatic tell-tale drain valves. The illustrations are unusually good and show the application of the "Vulcan" soot cleaner to various types of boilers etc. The frontispiece consists of a four-color reproduction of actual specimens of soot from different boilers and with different fuels.

## Book Reviews

**Conservation.**—A report just issued by the Commission of Conservation, entitled "Conservation of Fish, Birds and Game," directs attention to the great value of these resources to Canada. The volume is a report of the proceedings of a conference of the Committee on Fisheries, Game and Fur-Bearing Animals of the Commission, and contains a fund of information regarding the present condition and the necessity for protection of Canada's fish, birds and mammals. Canada is taking a prominent part in the international movement for the protection of wild life. A Migratory Bird Treaty between Canada and the United States is under consideration. Through the influence of the Commission of Conservation and other interests, bird reservations are being created, where the birds may find safe nesting and breeding places. The fur-bearing animals of Northern and Western Canada are being rapidly exterminated. This is clearly shown by the present report. To secure their more adequate protection, the Commission is advocating the amendment of the Northwest Game Act to place responsibility for its administration upon the Dominion Parks Branch, which already protects the animals in the Dominion National Parks. The future of the fisheries of Canada is dealt with in an able manner by the highest authorities in this country. That they are of great present value is recognized, but there is also a potential value in our oceanic and inland waters which, upon development, would mean the creation of new industries. To meet this condition, the Commission is suggesting vocational training and simple demonstration stations for the fishermen, that they may take advantage of the most practical and modern methods of their calling. The report is replete with illustrations applicable to the subject matter.

**Mechanical Engineer's Hand-Book**, by Lionel S. Marks, Editor-in-Chief, 1836 pages, (4½ in. x 7⅞ in.) limp leather binding. Published by the McGraw-Hill Book Co., Inc. N. Y., New York. Price \$5.00 net. This is the first edition of a handbook intended to supply both the practising engineer and the student with a reference book which is authoritative in character and which covers the field of mechanical engineering in a comprehensive manner. The general arrangement of the handbook is based on "Hutte" and is the work of a number of specialists with Professor Marks as editor-in-chief. The various contributors are authorities on the subjects which they have contributed, a guarantee that the information is not

## "PERFECTION"

THE NAME

THE DESCRIPTION

Sizes 16x6, 18x8, 20x10

**Edgar Bloxham, Inc.**

Grand Central Terminal Building

NEW YORK, N.Y., U.S.A.

Prices lower than any other lathe of same specifications because of volume of manufacture and fixed low percentage of profit over actual cost of production.

only reliable but that it at the same time follows the latest practice. While the subject of "Friction" and "Hydraulic Turbines" follow "Huthe" closely with the addition or substitution of American engineering data, the greater part of the book, particularly those portions which deal with engineering practice, are entirely new. The handbook is subdivided into fifteen sections well defined, dealing with major topics, and readily located by means of a thumb index. The first seven sections are to a large extent of a theoretical nature while the remaining eight are devoted to more practical subjects. The handbook contains a large number of well arranged mathematical tables of considerable value. The illustrations of which there are about one thousand, including charts and diagrams, have been carefully prepared and form a useful feature of this work. Engineers and students will find this a most valuable handbook, covering a wide range of subjects and dealing with each in a comprehensive manner. In addition to the thumb index there is one of important reference tables and a complete alphabetical index.

**War Office and C.P.R.**—The purchasing department of the British War Office for Canada is purchasing very extensively through the system and machinery of the C.P.R., and up to May 1, had placed orders in this country for \$13,000,000 worth of various general supplies, not including munitions. Since May 1, orders aggregating about \$4,000,000 have been placed. The Canadian Pacific, through Sir Thomas Shaughnessy offered to the War Office to handle the distribution of these orders without any charge other than any actual expenses, so they will not have any bearing on the earnings of the road.

## Manufacturing Cartridge Cases for 18 Pounder Shrapnel and 4.5 in. H.E. Shells

### Staff Article

*Not the least important among the many successes achieved by Canadian metal-working plants in the matter of munitions production has been that of the brass cartridge cases required for 18-pdr. shrapnel and the smaller high explosive shells. The output of cartridge cases has steadily developed in quantity, so much so, that in spite of the fact that comparatively few plants are so engaged, it is possible to now keep pace with the production of the corresponding steel projectiles to which the cartridge cases are a necessary supplement.*

**T**HIS plant, which is turning out approximately fourteen to fifteen thousand 18 pdr. shrapnel or 4.5 in. H.E. shell brass cartridge cases per day, receives the flat discs from several sources; and in order to keep a record on quality of output, these blanks are stored in separate bins, having the makers name attached, in order that faulty material may be traced back through the proper channels. These blanks, which are 6.22 inches in diameter, are punched out of rolled sheet brass, 0.380 inch thick. They are generally annealed at the makers mill, and are received at the case manufacturing plant in readiness for the first press operation.

Fig. 1 shows a general view of the press department, those presses in the

foreground being mechanically operated, central crank drawing units, and those, in the rear, of the heavy toggle type with the main mechanism located beneath the level of the floor. All of the presses are belt-driven from a line shaft overhead, one 75 horse power motor being used for the drawing presses, and three 75 horse power Westinghouse motors for the eight heading presses; the latter consisting of five-900 ton and three 1500 ton Ferracute toggle type products. A general idea of the shop layout will be had from Fig. 2.

### First Operation—Cupping

After the blanks are received, the first operation is that of cupping, shown in Fig. 3. This is performed on two Ferracute presses, each one capable of

producing from 7500 to 8000 cups a day of 22 hours. These presses are fitted with revolving turrets, so that, if necessary, the discs can be placed in position when clear of the punch; however, experience has shown that better results are obtained if the die is left permanently in a working position, as the possibilities of an operator being caught are comparatively slight, owing to the slow action of the moving ram. The cups are forced completely through the die, and are removed from below by another workman. A copious supply of lubricating material is automatically distributed to the punch and die, by an arrangement attached to the ram of the press and operated by its vertical movement, as shown in Fig. 5. The valve

plied from a tank overhead, through the hose F, and fed to the work through the pipe E. The drawn cup has an inside

Annealing the Cases

Owing to the drawing process hardening the metal, it is necessary to anneal the partly finished cases previous to each re-drawing operation. This is essential to restore the metal to the required ductility, in order to obtain satisfactory results. The cups are placed in large perforated, sheet steel boxes, which are placed on steel frame trucks, having several rollers on the upper surface to aid in transferring the boxes to and from the furnace chamber, which is also

rear doors of the furnace are controlled simultaneously, so that as one crate of cold cases enters at one end, a fully

While some authorities contend that water cooling affects the physical properties of the brass, it is the process

continuously, the workman placing the cups in the die as the ram ascends. In all instances, the pieces are forced through the die, falling out below. The dimensions of the case after the first draw show an inside diameter of 3.962 inches, outside diameter of 4.275 inches, and a height of about  $3\frac{1}{8}$  inches. Two Ferracute presses are working on this draw, each with a capacity of from 380 to 400 an hour. The cases are again annealed, going through the same process as already described, and are then taken to the second re-drawing operation, which is similar to the first in every respect. The finished dimensions of the case are now 3.912 inches inside diameter, 4.121 inches outside diameter, with a height of  $4\frac{1}{4}$  inches.

FIG. 7. PUNCHES AND DIES FOR CUPPING AND DRAWING OPERATIONS, 18 PDR. SHELL CARTRIDGE CASES.

heated lot is discharged at the opposite end. This crate, which has been in the furnace for about 40 minutes and has attained a temperature of approximately 1200 degrees F., is placed upon a specially constructed roller platform, that is lowered into a water cooling bath. Several immersions are made before the pieces are sufficiently cool to be handled. Running water is used, being pumped from a nearby canal.

After cooling, the cases are placed in wooden boxes in such a position that the pickling solution will have free access to the entire surface, and yet drain easily when raised from the bath. The pickling solution consists of a weak solution of sulphuric acid (about 20 to 1). The pieces are allowed to remain in the bath for several minutes, and are then immersed in a caustic soda bath and afterwards thoroughly washed in warm water to remove all traces of acid.

generally adopted by cartridge case manufacturers, the very best of results being obtained.

#### First Redrawing Operation

The first re-drawing operation is accomplished on Ferracute presses. The latter operates

FIG. 9. PART ELEVATION OF CARTRIDGE CASE MOUTH ANNEALING FURNACE.

FIG. 8. HEADING 18 PDR. SHELL CARTRIDGE CASES ON 900-TON PRESS.

#### First Indenting and Third Draw

Before going to the annealing furn-

aces, again, the cases receive their first indent. This is accomplished on a single acting Ferracute press, one such being sufficient to handle the output of the shop. Two men are engaged in its operation, one removing the finished piece as the other places the next one on the post and operates the swinging block. The press runs continuously, an indent being made at every other stroke. Fig. 6 is a sketch of the tilting post used when indenting the head. The post A is secured to the base of the press, and the block B which carries the post C is fitted in the slot and tilts on the pin D; the punch E is secured to the moveable ram. Following indenting, the cases are again annealed and taken to the third re-drawing press, where they are drawn to a length of  $5\frac{1}{4}$  inches, with an outside diameter of 3.984 inches and an inside diameter at the mouth of 3.843 inches, the punch being slightly tapered to leave the wall a little thicker near the head. Two Ferracute presses, with

similar capacity to that of the previous operations, are used on this draw.

#### Fourth Draw and Second Indent

The cases are again annealed and

FIG. 10. TAPERING 18-PDR. SHELL CARTRIDGE CASES.

taken to the fourth draw, where they are brought to a length of  $7\frac{1}{2}$  inches and an outside diameter of 3.855 inches, with walls 0.042 inch thick at the mouth, and tapering to about 0.077 inch near the head. Owing to the increasing length, three presses are required on this draw, the capacity of each being about 5,000 per day of 22 hours. The second indent follows, being really a repetition of the first, and being performed on a Ferracute press in like manner to that already described. To facilitate further operations, a small 5-16 inch hole is

this condition was not provided for, the trapped air would seriously affect the drawing operation. The cases are again annealed before passing to the fifth draw.

#### Fifth Draw and Preliminary Trimming

Owing to the extreme length, the fifth and sixth draws cannot very well be performed on a crank press, and for this reason other means are necessary. This plant has two large Bliss presses, the rams of which are operated by a rack and pinion, the length of the stroke being adjustable and the action controlled in the same manner as a belt driven planer. These two presses operating on the fifth draw have a capacity of about .220 per hour each. In addition, there are four large horizontal, double ended Ferracute screw presses, working on the fifth and sixth draws. The dimensions after the fifth draw show an outside diameter of 3.776 inches, with a tapering inside diameter; the mouth being 3.725 inches. The length is roughly  $9\frac{1}{4}$  inches. Following this draw, the cases are trimmed to a length of 9 inches on a Blount lathe fitted with a special trimming attachment. Two men are employed on this operation, one taking off and trimming while the other

lever. These presses operate at about six strokes per minute. A continuous flow of lubricant is supplied to the cases directly above and in front of the drawing die. This solution is pumped up from a central well, located below the floor, to a large tank overhead, from which it flows by gravity to the various machines. The dimensions after the final drawing operation show an approximate length of  $12\frac{1}{2}$  inches, an outside diameter of 3.7315 inches, and inside diameter, at the mouth of 3.680 inches, tapering to 3.635 inches near the head end.

#### Final Trimming and Heading

The cases are now trimmed to a length of  $11\frac{3}{4}$  inches. In Fig. 7 is shown the various draws with their respective punches and dies. The next operation, that of heading is shown in Fig. 8. This process is accomplished on several 900 ton mechanically operated Ferracute toggle presses. A turret is provided, having two sets of case holders, one for flattening and the other for final heading. Three men are in attendance, one operating the press and removing the case, while another places the next case on the post and revolves the turret; the third operator receives the cases and

FIG. 13. SOME OF THE MORE IMPORTANT GAUGES FOR 18 PDR. SHELL CARTRIDGE CASES.

places the cases on the arbor; the work being accomplished as fast as the men can handle the case.

#### Final Annealing and Sixth Draw

The cases now pass through the annealing furnace for the last time, and are then taken to the horizontal presses, shown in Fig. 6a. These presses are of the double-ended type, the cross-head which holds the punch being secured to either end of a central shaft, which is operated by a coarse pitch groove running along the whole length, the nut being secured in the bore of the main driving gear located in the centre of the press. The action of the punches is under automatic control, but to avoid any possibility of accident, an operator, is placed in charge of the reversing

places them in crates. The headed case is mechanically ejected by rods and levers controlled from below the moveable ram. The turret rides on a heavy spring and ball bearing to facilitate operation.

#### Mouth Annealing and Tapering

Before the tapering can be proceeded with, it is necessary to anneal the upper portion of the case, to allow of the diameter being reduced without buckling the stock. The furnace employed for this purpose (a section of which is shown in Fig. 9), holds six cases. the time required to heat the mouth of the latter to the desired temperature being from  $\frac{1}{2}$  to  $\frac{3}{4}$  of a minute. To insure uniform heating, which is absolutely necessary, the case rests upon a

FIG. 11. DEVICE FOR RETAPPING CASES.

FIG. 12. TOOL FOR FACING INSIDE OF INDENT.

punched through the centre of the indent to permit the free passage of air, as the punch enters and leaves the case. If

FIG. 15. SOME OF THE MORE IMPORTANT GAUGES FOR .5 IN. CARTRIDGE CASES.

vent of the large hydraulic presses, now employed on this operation, the plant here described had performed the heading on a powerful Bertram plate punch, fitted with special case heading equipment. Owing to the short length of the 4.5 cartridge cases, it is necessary to have a separate setting when machining the mouth end. The head is finished in a similar manner to that of the 18-pdr. cases, the machine tools employed consisting of special C.M.C. and Bullard lathes. Following this, the cases are taken to a number of small speed lathes fitted up with special chucks and cam attachments that allow of machining the mouths of the cases as fast as an operator can handle them. The rectifying and inspections are identical with those of the 18-pdr. cases.

An important factor in the manufacture of munitions is the handling of the scrap material, so as to prevent its locational accumulation. The scrap brass and copper in this particular plant are packed into blocks, 6 inches square by about a foot in length, this being procured through the medium of what is called a cabbage machine, made by the Longemann Machine Co., of Milwaukee, Wis. A 5-h.p. Westinghouse motor

duced 50 per cent. more shells than the company had thought possible from its equipment, but it stood by its agreement, although the bonuses paid were excessive, as they were only operative

FIG. 17. FINISHED 4.5 IN. SHELL CART- RIDGE CASE.

for a short time. According to the Iron and Coal Trades Review, the pay of one worker for one week, with his bonus, amounted to over \$150, and a number of others made nearly \$100 a week.

### COLLIERY GUIDE ROPE FRACTURE

A CASE of fracture in a colliery guide rope, which led to fatal results in a Scottish colliery, is calculated to afford matter for investigation by the metallurgist. The rope, which was made of steel

FIG. 16. PUNCHES AND DIES FOR CUPPING AND DRAWING OPERATIONS, 4.5 H.E. SHELL CARTRIDGE CASES.

operates the hydraulic pumps in connection with the cabbage machine, a final pressure of about 2,300 pounds per sq. in. being both necessary and attainable.

### INTENSIVE SHELL PRODUCTION

A LARGE contract for high explosive shells has just been completed by the Harrisburg Pipe & Pipe Bending Co., Harrisburg, Pa. The company, it is understood, established a new American high record for making projectiles per man and per lathe. It became necessary to stimulate production in the last few weeks to the highest attainable point in order that the contract should be completed by June 30, as any unexecuted portion was to be automatically cancelled if not completed by that time. Large bonuses on all shells made over a certain number were given to the workmen with this in view. The men pro-

duced 50 per cent. more shells than the company had thought possible from its equipment, but it stood by its agreement, although the bonuses paid were excessive, as they were only operative

strands, had been lengthened, the joints being welded into a solid mass of steel; the fracture occurred close to a weld. These ropes are exposed to numerous alternate bending strains in use, owing to the vibration of the cage, and it is possible that these had fatigued the metal at the plane of transition between the solid and the strand condition. In the case of bicycle frames, it is well known that the inserting of lugs of uniform thickness weakens the tubes at the points opposite to where the liners end, but that this difficulty can be overcome by tapering the metal of the liners and, by allowing this metal to give a little under stress, increasing the tube area over which the strain is distributed. The Ironmonger states that possibly a similar effect might be obtained in the case of these rope welds by a tubular sheathing, extending a short distance beyond the solid mass of the weld.

### ROPE DRIVE ADVANTAGES

I AM inclined to favor a rope drive in preference to a belt when the belt to be replaced is over 12 inches in width, says a writer in the Paper Trade Journal. Having had experience with both, he finds that the rope drive is much better than the belt. There are several advantages claimed by installing a rope drive.

1.—It is economical; the drive being cheaper to install than that by leather belting.

2.—The ease by which the power is transmitted to any distance or in any direction.

3.—There is less loss by slipping.

A single rope is carried round the pulley as many times as is necessary to produce the required tractive effort, while the necessary tension is obtained by passing the rope around a tension pulley weighted to give the desired strain.

The ropes used in rope transmission are of hemp, Manila, or cotton. Manila ropes are perhaps mostly employed.

The breaking strength of the rope varies from 7,000 to 12,000 pounds per square inch in cross section, and the average value may be taken as  $7000D^2$  when D is the diameter of the rope in inches. The weight of ordinary Manila or cotton rope is about .3D pounds per foot of length. For continuous transmission, it has been determined by experiment, that the best results are obtained when the tension on the driving side of the rope is about 1/35 of the breaking strength. The ropes run in V-shaped grooves. The co-efficient of friction for grooves with sides at an angle of 45 degrees may be taken at from .25 to .33. The formula for finding the horse-power transmitted is as follows:

$$H = \frac{\pi D^2}{825} \times \frac{200 - v^2}{107.2}$$

H—Horse-power transmitted.

D—Diameter of rope in inches.

v—Velocity of rope in feet per second.

The greatest tractive effort is obtained at a speed of about 84 feet per second. For higher velocities, the centrifugal force becomes so great that the effort is decreased; therefore, a rope should not run faster than about 5,000 feet per minute, and it would perhaps be better to limit the velocity to 3,500 feet per minute.

Rope pulleys differ from belt pulleys only in their rims. The inclination of the sides of the grooves may vary from 30° to 60°. The more acute the angle, the greater the coefficient of friction and consequent wear on the rope. The diameter of a rope pulley should be at least 30 times the diameter of the rope. When possible, the lower side of the rope should be the driving side, for in that case the rope embraces a greater portion of the pulley.

## MACHINISTS' INSTRUCTION COURSE—II.

By J. Davies.

**T**HE drilling machine is a real necessity to every machine shop, although its chief work is to make holes, yet it can be

FIG. 8.

used for a variety of other jobs, such as tapping, reaming, facing, boring, etc. There are many varieties of drilling machines, but we can consider them all in two classes, those in which the drill is moved to suit the work, termed

enough to reach to the outer edge of the table, and have the blacksmith draw out one end of the flat bar and turn down

a given surface on a piece of work.

The best and most frequently used drill for ordinary work is the twist

FIG. 10.

FIG. 11.

FIG. 9.

radial drills, and those in which the work must be moved to suit the drill, either by moving the table and the work together, or by moving the job alone.

In setting up a job such as a cylinder end, a pipe flange or anything with a number of holes in it on a radial drill be sure to try if the drill will reach every hole, before finally bolting down on the drill table. Make it a rule to never reset any job on any machine, until you are satisfied that it cannot possibly be done at one setting. The table of a drilling machine should be at right angles or square to the drill spindle, and before starting on an important job you may want to know that it is square to the drill spindle.

The best method by which to test the machine is as follows: Put a fairly stiff taper shank boring bar in the drill spindle, through one of the slots in the boring bar put a piece of flat iron, long

like a caliper leg to serve as a pointer. Fasten the flat iron in boring bar with a key or a set screw, lower the drill spindle until the pointer nearly touches the table, then pull the drill round by hand and try the table at four different

places, which is probably the most efficient tool found in the workshop to-day. It is formed by cutting spiral grooves in a round piece of tool steel, and has a cone shaped end on which suitable cutting edges are formed. Drills taper very slightly being biggest at the cutting end, this is to provide clearance in deep holes and prevent the drill choking in the hole. They also have what is called body clearance, that is part of the surface is cut away a short distance from the cutting edge back to the flute, thus reducing the friction between the drill and the sides of the hole, as without this body clearance the drill would soon get hot and become soft to a degree that would make it useless for further use. See Fig. 8.

Drill grinding is a very important thing for every apprentice to learn, as the result of drilling machine work depends largely upon the condition of the drill. No amount of instruction without actual practice and experience can make any one proficient in this art; all that

places. It is best not to let the pointer touch the table as the spring on the pointer might fool you; cut some slips of paper and use them for feelers lowering your pointer until you can feel it touching the paper.

If your pointer touches the paper the same way at the four opposite places, the table is accurate; if the table is found to be inaccurate and there is no means of adjusting it, note which is the low side of the table and allow for it in setting up your work.

You will find this pointer a very useful tool in setting up work in which the holes must be drilled at right angles to

FIG. 12.

can be done on paper is to point out ideal conditions and the results of inaccurate grinding of the cutting edges.

There are at least seven wrong ways of grinding to say nothing of a few original methods of every apprentice: (1) Too flat; (2) Too sharp; (3) Unequal cutting edges; (4) Unequal angles; (5) No lip clearance; (6) Too much lip clearance; (7) Unequal lip clearance. See Fig. 9.

1. The result of grinding too flat forms a hook-like cutting edge and it is very hard to get a round hole. The drill ground in this manner is very apt to get away from the centre punch mark, and must be watched very closely.

2. Too sharp a point puts unnecessary strain upon the machine and if you happen to be drilling thin plates, the drill point comes through the plate before the full size of the drill is entered into the metal, this allows the drill to wobble all over the job and causes a very irregular shape hole.

3. Unequal lengths of the cutting edge form a serious defect as this results in the hole being too large, although sometimes the fact of a drill possessing equal angles and one cutting edge longer than the other, can be turned to advantage, as in a case where you want a hole just a shade larger than the drill, or between the sizes of standard drills, otherwise, as it often happens especially in a small shop, you will have to use a drill with the margin considerably worn. Wear on the margin or land in Fig. 8 leaves the drill without sufficient clearance, so that it is apt to bind in the hole, and also drill a little small. In a case of this kind it is a distinct advantage to grind one cutting edge longer than the other.

4. If the point of the drill is in the centre but the angles of the cutting edge different all the work will be done by one cutting edge, and the drill will be crowded over to one side, which has a tendency to bind the drill, also make the hole too large. See Fig. 10.

When both the angle and the length of cutting edges are wrong it is impossible for the drill to give anything like satisfaction, it will be working under the very bad conditions shown in sketch Fig. 11. The support which a properly ground drill receives from the metal being drilled is entirely lacking.

5. If the drill has no clearance it simply will not cut and any attempt to make it cut by force will only end in disaster, usually by splitting the drill up the web. On the other hand if the drill has too much clearance it is liable to dig into the work and become loose in the drill socket. If you are using a straight shank drill, it would most likely slip around in the drill chuck and the edges also will keep breaking away because there is not sufficient metal behind them to support the edge.

As the drill becomes shorter the centre becomes thicker, because the web of the

drill is made thicker towards the shank to give the drill strength. To overcome this thin the edges taking care to keep the point central. The three main features to aim at in grinding drills are: (1) equal lengths; (2) equal angles; (3) proper clearance. The angle recommended by most drill makers is 59 degrees on each side as shown in Fig. 12.

### ATTACHMENT FOR SHELL BANDING PRESS.

By John S. Watts.

THE sketch shows a rest for attaching to the side of banding press, which forms a convenient place whereon to rest the

ATTACHMENT FOR SHELL BANDING PRESS.

shell while hammering the band into the groove in the shell. It is necessary to give the band a blow or two with a hand hammer to set it into its groove so that it will stay in position on the shell when the shell is stood in place on the press.

The rest is simply a piece of steel plate bent to the shape shown and secured to the side of the banding press with two cap screws in the position shown in sketch. The shell can then be laid on this rest while hammering the band into position.

### ACTIONS IN EMERGENCIES

By J. Hamilton.

WHAT a person would actually do in a case of emergency is a debatable question. We are all prone to believe that we would or could control our actions under certain conditions; but in many instances an exactly opposite effect has been the result. The reaction of the nerves, due to any sudden news or local disturbance, so affects the brain of the average person, that they are plunged into a state of semi-panic or bewilderment, with a temporary loss of thinking power; consequently, predetermined actions are forgotten, and we are forced to obey a power, over which we apparently have no control. The spirit is often willing, but the flesh is nearly always weak.

In a large factory some time ago the main belt from one of the motors broke, striking and destroying one of the water sprinklers. If the men in the shop had been told that this particular mishap was expected, they may or may not have acted differently, but what did occur was equally as sudden and complete as

that of the breaking of the belt, with the subsequent distribution of dust and flying water. Without a thought of what had happened, the entire gang of men, with the exception of the foreman, stampeded for the doors, falling over themselves and others with the one object of reaching the outside. However, they were no sooner outside than the "gray matter" began to settle, and, returning to the interior, they found the foreman (somewhat unstrung) watching a gradually decreasing flow of water from the broken sprinkler.

An interesting test was recently made to determine the stability of a young lad who had been continually saying what

he would do under certain conditions. The question of bravery under fire of shot and shell was being discussed by several men in the shop, and this young fellow intimated that he could stand up to the ordeal alongside of anyone; so to show the others and prove to him the fallibility of the majority of humans, we chose a time when he was absent from his lathe, and, taking the heavy or "light" end of several parlor matches, inserted them in the large gear of the back shaft, the matches being secured by a small quantity of belt dressing. When he returned to his lathe and pushed over the shifter, the effect of the "machine gun" can be well imagined. Where the blood had gone to is doubtful, but it was certainly not in the "pale" of his face.

### "SHRINKING-IN" A SHAFT

J. R. H.

AS the years roll by, we are constantly adding to our store of knowledge, and while casting about for useful furniture to occupy the vacant cells of our upper storey, we sometimes fasten our hook upon a unique object, which is of little material value, but serves the purpose of showing to what extent some rooms require refurnishing, and some of the furniture remodeling.

A few years ago I was engaged shrinking a large cast iron collar on a shaft. I had machined the parts in readiness for the shrinking operation, and was heating the collar to place on the shaft, when a young man who had been doing fitter's work for several years came to watch the operation. When the collar was sufficiently heated,

I placed it in position on the shaft and in a few moments it took hold. The man inquired if it was not possible to "shrink in" the shaft. Not grasping his meaning I asked what he meant, and he replied; would it not amount to the same thing to head the shaft instead of the collar? After a little explanation, he left me, taking with him a useful piece of furniture, which up till that time had been obscured by dust, and was probably blocking the passage to more efficient material.

If your brain is to be a storehouse, examine each piece as it goes in, to avoid accumulating a lot of junk, that in a short time may cover up or obscure some more useful material.

### ANGLE ATTACHMENT FOR TEE-SQUARE

By H. M. F.

IT often happens when making drawings that certain parts of the object being drawn are located at an angle with other surfaces. With the tee-square used in the usual manner it is quite difficult to obtain these surfaces, as a protractor must be used which takes up considerable time. To overcome this difficulty a block may be fitted to the tee-

ANGLE ATTACHMENTS FOR TEE-SQUARE.

square, as shown by the accompanying illustration. This consists of a knurled screw and a rectangular piece of wood, having the corner slightly rounded, which is placed on a tee-square in the manner illustrated.

To use this tee-square for drawing on an angle it is necessary to first locate on the line at the desired angle, after which, by swiveling the block until the tee-square matches this line, the remaining angular lines are drawn in the usual manner by sliding the tee-square up and down and using triangle.

### MICROMETER DISCS FOR USE IN SETTING CALIPERS

By F. Seriber.

IT frequently happens in measuring work that micrometers handled in the usual manner do not adapt themselves very well to the condition, and in this case some other form of measuring must be resorted to.

FIG. 1. ILLUSTRATING DIFFICULTIES IN MEASURING CERTAIN PARTS OF OBJECTS.

Two examples showing work of this nature are illustrated by Fig. 1, the conditions being obvious. In the diagram at the left the dimension A cannot be

FIG. 2. METHOD OF USING DISCS ON A MICROMETER FOR SETTING OUTSIDE CALIPERS.

measured owing to the projection B interfering with the frame of the micrometers. In the diagram at the right it is necessary to measure at C, which is about two inches from the end of the part being measured, and likewise this is impossible with an ordinary micrometer.

Recognizing this difficulty, a pair of discs, as illustrated in Figs. 2 and 3, are

FIG. 3. TYPES OF DISCS FOR USE AS SHOWN IN FIG. 1.

used in the following manner. Referring to the illustration, the discs are placed on the anvil and spindle of the

micrometer, with a spring A to keep them in place. These discs have the surfaces X ground so that a reading taken from these surfaces will coincide with a reading taken in the usual manner without the discs. In using these discs a pair of ordinary spring calipers are set, as illustrated, using extreme care not to force the discs out of place; after this the work to be measured is calipered in the usual manner by the sensitiveness of the touch as the spring calipers are tried on the work.

A convenient pair of discs used for setting dividers is also shown in Fig. 3. In setting the dividers to these discs the point of the dividers are set to the groove Z. These two pairs of discs will be found very useful in getting around many of the odd jobs which present themselves in the day's work, and will greatly increase the usefulness of the micrometer caliper.

### BRITAIN FAVORING CANADIAN EXPORTS

THE Controller of the British Department of Import Restriction has notified the Trade and Commerce Department, Ottawa, that he is prepared to consider favorably applications for licenses for the export to England from Canada of goods on the prohibited list. The condition attached, however, is that the goods in question were ordered before the date of the prohibition and are landed in the United Kingdom on or before September 15.

The list of prohibited goods is long and consists of goods whose importation is wholly restricted and others for which licenses must be obtained. The dates of prohibition vary from March 1 last to recent periods. Ivory, leather, paper, cardboard, sewing machines, furniture and many other such commodities are on the lists in question, Canadian exporters of such goods as pulp and paper, cardboard, furniture, etc., whose importation is allowed by license only, and as a general rule restricted to two-thirds the normal consumption, are being favored as far as possible by the British authorities in the granting of these licenses, it is learned. It is a species of preference within the Empire.

Copies of the Canadian National Exhibition prize list may be obtained by writing Dr. J. O. Orr, general manager, Toronto.

The Toronto Board of Trade urged the C.N.E. directors to run the Fair for three weeks as far back as 1885, but the management thought two weeks quite long enough.

# CONTEMPORARY WAR ARTICLES

Embracing Information and Data Drawn from a Variety of Sources Relative to and Arising from the Prosecution of this Many-Sided European War

## MACHINING DEPARTMENT OF BRITISH NATIONAL SHELL PLANT

IN our August 17 issue through the courtesy of The Engineer, London, England, we were able to submit to our readers a racy though none the less interesting illustrated article covering the forging department of one of Britain's National Shell Manufacturing Plants. In the present instance, and from the like source, date and illustrations relative to the shell machining and finishing departments are featured.

### Establishment.

About a mile distant from the forge department there is situated that in which the forgings are machined into finished shell cases. The history of this branch of the factory is one of the romances of the war. On August 30, 1915, the site was viewed for the first time. It was then under a crop of oats.

and this part of the work was completed by Christmas. The roof trusses followed, but bad weather came along, and it was not until the end of February that the glazing of the roofs was finished. The whole factory was completed by March 20, that is to say, everything down to the floors and the concrete foundations for the machines was ready.

Naturally the provision of the machines for the factory could not be accelerated beyond a certain limit, but as they arrived, section after section of the workshop was set going. Some of the machines arrived before the end of the year. Indeed, by January 12, that is to say, more than two months before the factory could be said to be complete as a building, twelve women were started on the machining of shells. The number of workers was increased to keep pace with the growth of the factory, those parts not completed being

a third shift were started on April 12 and May 1 respectively. By the latter date a third of the factory was in full working order. On the date of the Engineer representative's visit, it was rapidly approaching its full contemplated staffing. In fact, it was then running from 6.30 on Monday mornings until 10.30 on Saturday nights, with breaks only for meals, and was increasing its staff at the rate of 100 per day.

### Constructional Features

The factory, not counting the offices, mess-room and other adjuncts, covers an area of several acres. The ground was not level to begin with, and had to be filled in with ashes, in places up to a depth of 4 ft. Between two and three thousand tons of ashes were thus accounted for. The columns and roof trusses contain altogether about 1800 tons of steel, and there are about 400

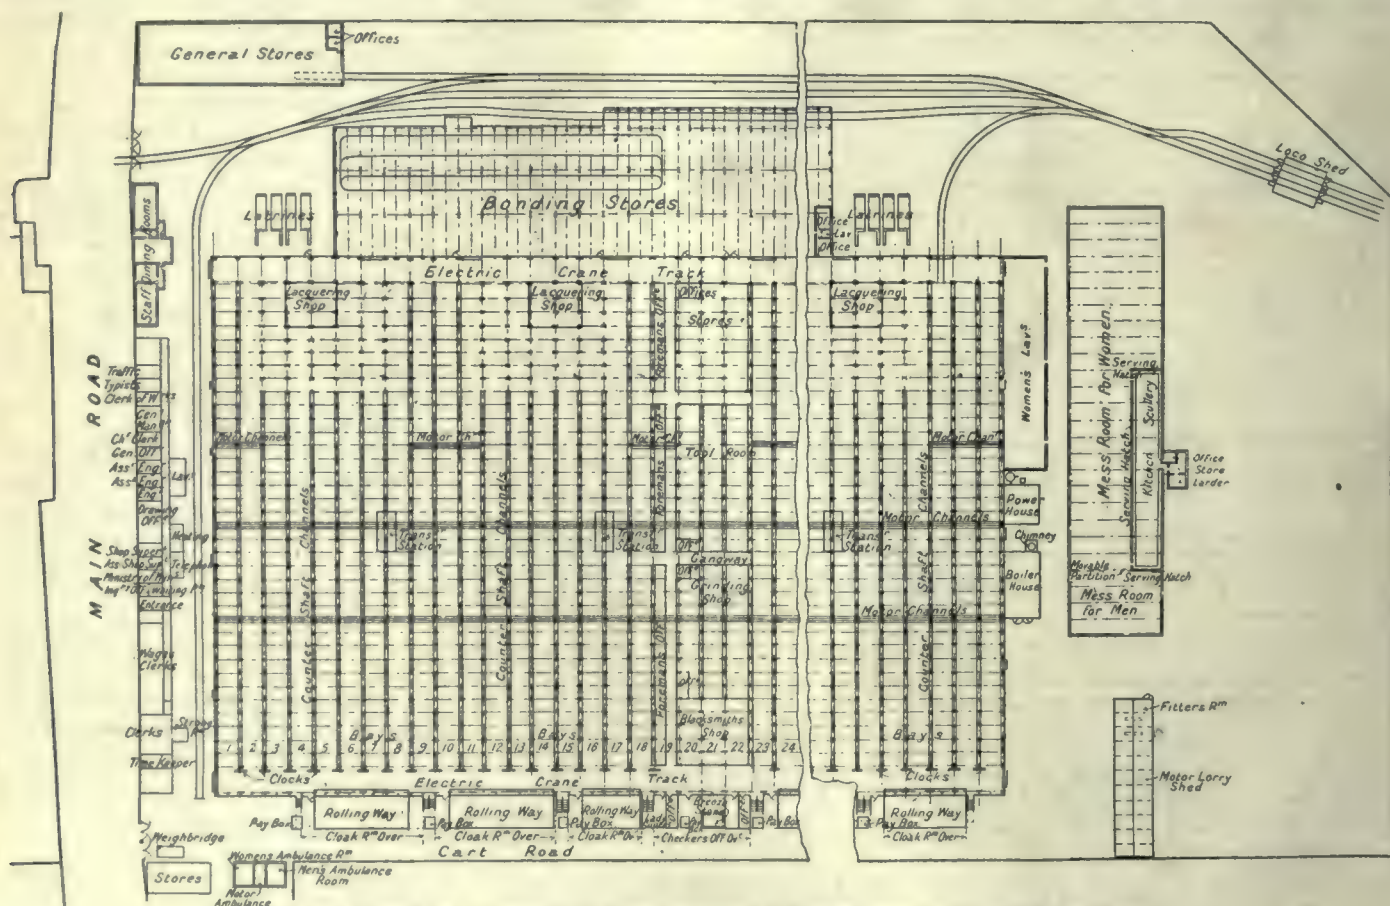

FIG. 1. LAYOUT OF MACHINING DEPARTMENT, BRITISH NATIONAL SHELL PLANT.

On September 2, half a dozen workmen started operations. By October 6, all the foundations were in, but even before this, namely, on September 18 the erection of the columns had been begun,

meanwhile screened off by boarding from those which were at work.

At first the operators worked on one shift lasting eight hours, but as more operators became available, a second and

tons of glass used in the roof. In addition, there were the galvanized iron sheets for the sides and all the details of the equipment to be reckoned with. Naturally one of the first problems to

be faced was the connection of the chosen site with the nearest railway. A main line passed the works about 300 yards away, but, to get to this, the line had to be carried from the works across a main road and down a bank at an incline of 1 in 25. The line was started on September 6 and with all its connecting sidings inside the works was ready for use by November 18. Now that the work of erection is completed the line is used principally for the removal of the finished shells.

#### Training the Workers

So much for the material difficulties. The difficulty of getting suitable operators was no less great, and it was met with equal courage and energy. At a recent date the factory was employing 1725 girls and 314 men, the men being largely employed in setting up and keeping the machines in order. In fact it may be taken as correct that all the actual shell making and finishing was in charge of girls. The majority of the laborers, that is to say, those not occupied on the machining of shells but on such work as carrying the shells from one machine to another, were women. All this female labor had to be collected and passed as the works progressed.

By the principle of specialization explained in the forging article, the machine tool-makers have been able to supply machines which are readily operated and handled. In few cases is more than a month required in which to teach a future operator her work, and in many instances fourteen days is sufficient. The operators themselves, if properly trained, make excellent instructors.

All the workpeople have been trained by the firm in charge of the factory. This applies not only to the women but to the men in most cases. The superior foremen were mostly shell machinists before the war at one of the big armament works. The under-foremen have been drawn from many classes, and

shells from the forge enter the works and at the top left-hand corner are the gates through which the machined shells pass out of the works in railway trucks. Between these gates, flanking the main road, are the offices. These are all on one floor. Their construction is interesting. The inside, outside, and partition walls are made entirely from cement

slabs, 2 ft. square and  $2\frac{1}{2}$  ins. thick. Primarily intended for sidewalk making, they form excellent building material, for they become dry and

hard very quickly. They are cemented together along their edges, so that the walls everywhere are only  $2\frac{1}{2}$  ins. thick. In addition to the cement, small steel U-shaped pieces are employed to bind each neighboring pair of slabs together. The inside and outside walls are stiffened at intervals of 29 ft. by pillars of reinforced concrete, and, on the outside, facing the road, the wall is rough cast.

The main factory extends to a considerable depth behind the offices. It may be described as consisting of numerous rows of steel columns, forming a corresponding number of manufacturing bays, each 18 ft. wide and provided with a pointed roof glazed on both slopes. The side walls are of galvanized iron. Three of the bays, namely, those numbered 20, 21 and 22, are given over to a blacksmiths' shop, where the tools used in the machines are forged and dressed; a grinding shop where the tools are ground to shape and sharpened after being forged; a tool room where repairs

FIG. 2. ARRANGEMENT OF ROLLING WAY.

FIG. 3. ATTACHMENT OF MACHINE TOOLS TO FLOOR.

have been trained for their special work since the factory was started. A few skilled blacksmiths and tool fitters are employed. Such men, of course, required little or no training, as they were already qualified. A few male tool setters are to be found in the works. These men have been "lent" to the firm after having been trained, say, in a technical institution. At the factory they are principally employed to train women tool setters, who when proficient will take over the entire work of this nature. The total number of men employed at present is not at all great. As time goes on the number will decrease, while the number of women will rise. It is expected that ultimately the number of male employees will fall to something less than 5 per cent.

#### Lay-Out of the Factory

In Fig. 1 is shown a block plan of the factory. At the lower left-hand corner are the gates through which the steam wagons carrying the rough

FIG. 4. DIAGONAL VIEW IN MACHINE SHOP, BRITISH NATIONAL SHELL PLANT.

and equipment for the machines are carried out and produced, and a store-room whence tools, oil and other details required by the operators are issued. The nineteenth bay is occupied by foremen's offices.

Although the blacksmiths' shop is surrounded, as it were, by the rest of the machinery, no inconvenience is experienced. The place of steam hammers has been taken by electrically-driven hammers using compressed air as the medium instead of steam. The smoke from the smiths' hearths is drawn by fans through overhead trunks and delivered through the roof.

Looking at the bottom of Fig. 1 where the incoming cart road is shown, it will be noted that opposite the four non-productive bays an annexe is provided as offices of the lady superintendent, her assistants and so on. In line with this annexe, and situated so that they may readily serve all the machine bays, are some rolling ways. These rolling ways are built-up structures of wood and greatly facilitate the passage of the forgings from the steam wagons to the inside of the works. The sketch—Fig. 2 will explain their construction. The galvanized iron sheeting which forms the side walls of the building is stopped short some distance above the level of the shop floor. The rolling way is built beneath, part inside and part outside. The outside edge of the rolling way is at such a level above the cart road surface that when the steam wagons come alongside and let down their side doors, the shells may be rolled right on to the incline, whence they travel by gravity down to the buffer inside the building. From the table within the wall, the operators can readily carry the shells to their machines as required.

#### Machine Tool Arrangement

The passage of the product within the factory is in a continuous straight line. Each bay may be said to be self-contained. If we pass down a bay, starting from the rolling way end, we will find that on either side of the central passage way is a row of machines, each one of which is different, and performs a different operation on the shell forging. A shell once taken from the rolling way into a particular bay remains in that bay and on one side of it until, having been passed from one quarter to the next, it emerges at the opposite end completely machined. Just as a sound system of lines of communications is required by an army, so, too, in a modern engineering factory, efficiency requires a sound system of distribution for the work. Crossing of the lines of communication in the one case and the

lines of distribution in the other do not promote good output.

What we may call the lines of control of the factory are at right angles to the lines of distribution of the work. It will be gathered that if we imagine a line drawn at any point of any bay at right angles to its length and passing through a certain type of machine, all the machines in the other bays and lying on this line will be of same type and will be performing the same operation. Over each such row of machines a separate foreman is placed, so that each foreman has one and only one class of machine under his charge. It may be remarked that certain of the operations are simpler and can be performed more quickly than others. To prevent congestion and to secure the maximum output, the quickest and easiest operations are made to set the pace, the more difficult operations being brought into line by providing more than one machine for them in each day. Thus walking down any bay in the direction in which the work travels, we may notice in places that two or more successive machines on either side are similar and are performing identical work.

#### Cutting Lubricant Arrangements

In this factory the machine tool lubricant used is a soap-and-water compound. The provision of this cutting fluid in a works of the size and nature of that here described is no small nor insignificant matter. The arrangement adopted is to provide central pumping stations for the fluid, with an overhead delivery pipe with branches to each machine and a trench or gulley leading into a main trench and well, wherein the used fluid is collected ready to be strained and returned by the pumps to the overhead delivery pipe. There is one such pipe on each row of columns, so that each pipe serves two rows of machines. The lubricant having done its work, drips off into the trench beneath the machine. This trench is of concrete, there being one such trench for each row of machines. At the centre of the shop, running at right angles to the trenches, is a main trench with which the others drain; for this purpose each half trench is given a fall of 5 in. towards the centre of the shop. At each end of the main trench there is a pumping station and a suds well, 5 ft. in diameter by 18 ft. deep.

#### Machine Tool Foundations

In ordinary practice the machines in an engineering workshop are fixed in position by means of bolts embedded in foundations of concrete. By loosening the nuts the machines may be removed, leaving the bolts projecting from the concrete foundation. It is not quite easy by this means to secure a satisfactory job. Considerable pains, for instance,

have to be taken to ensure that the bolts shall when the concrete sets, register accurately with the holes in the machine base plates. At this factory, the machines are fixed in a manner which is somewhat unusual, and which, although open to certain objections in a less critical time; undoubtedly has the merit of expediting installation. The machines are simply cemented down across the concrete suds trenches, no bolts whatever being used. The sketch, Fig. 3, will make the method quite clear.

The suds trenches of two adjacent rows of machines are united throughout their lengths by a level layer of concrete. From this level layer the columns supporting the roof rise. The arrangement gives the operators plenty of room to pass behind their machines for cleaning and adjusting them, and at the same time results in the columns being situated where they are least obstructive of room. The columns in general are supported on concrete foundations, 3 ft. square and 3 ft. deep, and are held thereto by means of bolts 18 in. long. Certain of the columns are heavier than the average. For these the depth of the foundations blocks is increased to 4 ft. It will be gathered then, that the suds trenches and the foundations for the columns form a continuous mass of concrete, which was laid as far as possible without a break.

The floor of the factory, except at the suds trenches, is of wood—a factor which adds not a little to the comfort of the workers. The ground, as we have said, was first levelled with ashes. Thereafter, old railway ties were laid down at 3 ft. intervals transversely between the columns. These directly support the floor, which is of 2 in. battens running longitudinally. Further to add to the workers' comfort, the factory throughout is steam heated. For this purpose, steam pipes are carried by each row of columns at a height of about 10 ft. above the floor level. The glazing of the roof has been tinted blue by stippling on the inside with washable distemper. This keeps out the direct rays of the sun, and has a very pleasant effect.

#### Machine Tool Drives

The problem of how best to drive the immense number of machines in use seems to have been very satisfactorily solved. Two factors had to be kept prominently in mind. First, the driving arrangements should not materially obstruct the natural lighting of the factory. It is quite common in certain engineering workshops to find the machine shops in a state of semi-darkness because of the tangle of belts which are required to drive the machines. Secondly, the drives to the machines should be well out of the way so as to avoid accidents.

This, if belts are used, as is the case here, is a point of the greatest importance in a factory employing female labour. These two points have been well attended to, and, in addition, the method adopted does not, we believe, result in an excessive loss of power in the transmission.

Figs. 4 and 5 are sufficient to show that the natural lighting of the factory is all that could be desired. A view is got along one of the bays in operation. It will be seen that the machines in the bay are all driven from one overhead shaft, which runs down the centre of each bay. This shaft is carried from the underside of the roof trusses, which ensures as high a position as possible; it is driven by electric motors, which are supported high up in the roof.

ed inside. This work is carried out in rooms situated at the outgoing ends of the bays. These rooms are each spread over the width of two bays, and are separated from the rest of the building by walls of asbestos board  $\frac{1}{4}$  in. thick nailed to the inside of a framework of wood. In each varnishing room there are several gas-heated drying stoves, where the shells after varnishing are baked for two hours.

Leaving the lacquering rooms, the shells are conveyed to the bonding store, an adjunct to the main building; this is screened and locked off therefrom. The bonding store may be said to be private Government ground. Here Government officials take delivery of the shells, which are finally examined and, if found satisfactory, painted externally. The ar-

Recently, however, it has been proposed to reduce the machining required by forging the nose pieces to approximate shape under drop hammers. The objection to this course earlier has been due to the possible difficulty of cutting into the hard skin which was formed on the surface of the pieces during the forging process. The difficulty has now been surmounted by removing the scale or skin in question by sand-blasting, before machining.

#### Management and Welfare

We have already indicated certain features in the working of the factory bearing on the all-important matter of the health and welfare of the girl workers. Some other facts connected with this subject may be stated by the

FIG. 5. LONGITUDINAL VIEW IN SECTION OF MACHINE SHOP, BRITISH NATIONAL SHELL PLANT.

There are either two or three of these motors in each bay, as the case may be, each driving a portion of the line shafting, which serves from 12 to 20 of the machines below. At the roughing-out end of the shop, the work done by the machines is of a heavier nature than at the finishing end of the shop, so that one electric motor is powerful enough for a greater number of machines at the finishing end than at the roughing end. From the main shafting down the centre of the bay belts slope down right and left to individual countershafts attached to girders running between the columns. Each machine thus has a separate countershaft. It is situated slightly to the rear of the machine and quite 10 ft. above the operator's head.

When the shells have been completely machined, they are varnished or lacquer-

rangements made for pointing the shells are interesting. As they come into the bonding store they are hung separately on hooks suspended from an overhead runway. Thus supported, they can be readily examined and painted, the entire operation involving the latter being conducted by a few women, each of whom is provided with a sprayer, which, served by one pipe carrying paint and another carrying compressed air, sprays the paint on to the shells when the trigger is pulled. The shells are taken down from their hooks when they are dry, being thereafter tested over their coat of paint with a gauge, following which they are ready to be stored or dispatched.

Nose pieces at the time of this writing were being machined from sections of round steel bars sawn to length.

way of conclusion. The control of the girl workers, so far as what may best be described as domestic matters are concerned, is in the hands of a principal lady supervisor. Under this lady are three sectional lady supervisors, each responsible for a section of the works. Under each sectional supervisor are two assistants. In addition to these, there are one lady canteen supervisor and three canteen assistants. Three fully trained nurses have been engaged, one at least of whom is always on duty. These nurses attend to any cases of accident or sudden illness, and keep a watchful eye on the general health and condition of the girls. Speaking of accidents, it may be remarked that up to the date of this writing, none requiring the use of a stretcher had occurred, though these are provided for. As for

minor accidents, such as cut and bruised fingers, it is found that on the whole these are more numerous than with men employees. This is explained quite satisfactorily by the existence of a rigid rule which requires every mishap, however small, to be reported and attended to at the ambulance room, whereas with male workers many a cut and so on is attended to by the workers themselves without a report being made.

### Plant Hours

The hours of the factory are divided into three equal shifts, namely, from 6.30 a.m., to 2.30 p.m., from 2.30 p.m. to 10.30 p.m., and from 10.30 p.m. to 6.30 a.m. Half-way through each shift there is a break of half an hour for a meal. Particular inquiry was made as to how the efficiency of the night shift compared with that of the others. As the workers are girls, it was expected to find quite a perceptible reduction of the output during the third shift. Experience would teach us to expect it even with men. From signed statements showing typical outputs over the three shifts separately, on not a few of the operations the output during the third shift was distinctly better than that during the first and second. In a few cases it was slightly poorer. Taken on the whole, the figures shown enable us to say with perfect certainty that the efficiency of female labour in this factory does not fall off during the night.

When the works were designed and laid out arrangements were made for the employment of girls on the smaller operations only, and to the extent of about 10 per cent. of the total employees arranged for, but before the factory started work the scarcity of men was so severely felt, and the experience proved so satisfactory elsewhere, that it was decided to arrange throughout the factory for girls to operate the shell machines, and, as stated above, it is expected that the proportion when the factory is in full working order will be 95 per cent.

This alteration entailed considerable modifications to the lay-out of the factory, which had to be developed after the factory had started work. It was found necessary to build additional ambulance rooms, cloak-rooms and rest-rooms for the girl workers on a larger scale than had been allowed for on the assumption that men were to be the chief workers in the factory. A large canteen has been erected, and arrangements have been made for cooking and supplying hot meals at as low a cost as practicable.

Two facts predominate as a result of a visit to this plant. One is the apparent ease and willingness with which the girl workers have taken up their new

work and the efficiency with which they perform it. The work they have to do involves lifting weights up to 80 lbs. or so—about the limit for a woman—and standing for eight hours, except for the meal-time break. It might well tax the strength of many a man. Yet they all seemed cheery and happy, and went about their work with a zest which is not always manifested among male workers.

Our other impression is one more difficult to express in suitable words. It takes the form of a consciousness that behind the good work and efficiency of the girls and the factory as a whole, there is evident to those who can see it the dominating influence of a few master hands, those, namely, of the men—the engineers, in the very truest meaning of the word—who planned the construction and working of the factory and of the machines and appliances with which it is equipped.

This influence is none the less evident because it is silent, yet silence on the subject is apt to mislead the country, and certainly has misled it and our Allies. It is, in our opinion, most desirable for all, even the enemy, to learn that Great Britain is not asleep, that her engineers realise what is required of her and that they are straining every nerve to do their duty. Self-depreciation is largely founded on ignorance of one's true worth and capabilities. From what we know, not only at the factory described in the two articles, but elsewhere, we can tell all whom it may concern that self-depreciation, at least in the matter of the supply of warlike material, is unreasonable, absurd and foolish.

### CASE HARDENING WITH CYANIDE

FOR many purposes a thin, hardened outer surface is required on wrought-iron or steel articles. This can be quickly secured after finishing by the use of potassium cyanide. All iron and steel, roughly speaking, will absorb carbon when, at a temperature of from 800° to 850° Cent., or in smithy terms from bright to cherry red. This is taken advantage of in surface-hardening, the metal being heated to this point, preferably in some form of muffle, even rough. At this stage the metal can be plunged into a bath of melted cyanide or rubbed with a lump of cyanide held in a pair of tongs until the metal becomes dull red, after which, reheating to the hardening temperature, and immersing immediately in cold water is done to secure the greatest hardness possible. Properly done, this should turn a file. A better plan, where the size and shape of the articles permit, is to coat a piece of leather with powdered

cyanide and press the heated articles on this, repeating the heating and pressing several times, afterwards reheating and quenching. For deep case-hardening, the usual method of packing and heating must be adopted.

### A STEP IN THE RIGHT DIRECTION

AN important work has begun in Indianapolis with the teaching of the English language to every alien employed in a local factory. It is the outgrowth of the national "America First" movement, having for its object the training of the foreign-born resident for citizenship.

In no country is it possible to exercise intelligently the privileges of citizenship without having first an adequate understanding of the prevailing tongue, and of what such citizenship means. So the work of education must begin at the bottom.

There are in numerous Canadian and American factories, many aliens who have never signified their desire to become citizens. Some have only a meager knowledge of English. Our country cannot grow as it should when many of its inhabitants remain ignorant of our language, and of the national customs and habits.

Now, as never before must we awaken to our responsibilities in this matter. The new education may be slow but it means preparedness.

### WAR AND ENGINEERING

IF there is any fact that the war has driven more deeply into our mind than any other, it is that engineering science, next to unquestioning patriotism, is the greatest single factor in modern warfare. This fact the engineers see clearly. They know that money and men are not enough. There must be some thinking force to turn the money into guns and to prepare a way for the soldiers. While the civilian engineer is by no means fitted to plunge into active military engineering, he is prepared to make the most of a course in training.

In a recent issue the "South African Mining Journal," Johannesburg, stated that the Rand Water Board has decided to proceed with a modified scheme for supplying the Witwatersrand with water from the Vaal River. Originally the scheme was one for impounding 20,000,000 gallons of water and providing plant for pumping 10,000,000 gallons to the Rand. It has now been decided to proceed with the erection of the barrage on the original lines, but to instal a plant capable of dealing with only 5,000,000 gallons. The cost of the scheme is estimated at \$3,790,000, including an amount of \$210,000 already expended for surveying, etc.

# PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

## AUTOMATIC DISTRIBUTING VALVE FOR STEAM PUMPS

**D**ESIGNED to meet all the requirements of a successful device for controlling the distribution of steam in pump cylinders, the Attwood Patent Operating Valve

right end of valve A through ports M and J to main exhaust port K, while port L is covered to the exhaust port J and steam accumulates at left end of valve A through port H and moves valve A from left to right, opening port H to live steam and port I to main exhaust,

and general purposes. Fig. 5 is a cross section through one end of the steam cylinder showing the main steam port entering the lower side of the cylinder bore.

Fig. 6 is a cross section through centre of steam cylinder and steam chest, show-

FIG. 1. SECTION OF CYLINDER ILLUSTRATING OPERATION OF DISTRIBUTING VALVE.

FIG. 2. SECTION OF CYLINDER ILLUSTRATING OPERATION OF DISTRIBUTING VALVE.

is applicable to both horizontal and vertical pumps without any change. An explanation of the working is given in the following illustrations:

Figs. 1 and 2 show a sectional plan of steam cylinder and steam chest, exposing the two piston valves A and B, the slide valve C and also the steam piston. The piston valve A engages slide valve C, which opens ports H and I to live steam and to exhaust port K alternately in order to operate the steam piston.

Live steam is admitted to centre compartment of steam chest containing the piston valve A and slide valve C. When the valves are in position shown in Fig. 1, steam is entering cylinder by port I, and exhausting from cylinder by port H to main exhaust port K. Piston has completed its stroke from right to left by uncovering port F, and admitting steam by ports F and D on to end of piston valve B, which is now moved to the position shown in Fig. 2. Ports N and O admit live steam from the centre compartment of chest through the inside of piston valve A to the outer ends of same.

In Fig. 2 piston valve B has uncovered port M, and steam is exhausted from the

K. Ports D and P are now open to exhaust the valve B to main exhaust port K and when steam piston has completed its stroke from left to right the reverse operations are repeated through the ports E, R and G respectively. Valve A overruns ports L and M at each end of its stroke thus preventing waste of steam.

Figs. 3 and 4 are front elevations

of screw tappings for steam, exhaust and lubricator connections. Fig. 7 is the same type of pump as Fig. 3, but fitted with extra long stretcher and piston rod which is the usual practice when used for pumping tar and chemicals, to prevent the fluid being carried by the pump rod into the steam cylinder.

Figs. 8 and 9 are front and side views of vertical outside packed ram steam pump, especially

FIG. 3. ELEVATION OF INSIDE PACKED POT VALVE PUMP.

FIG. 4. END VIEW OF FIG. 3.

tion and end views of the Attwood patent horizontal, inside packed, pot valve pump, which is designed for medium pressure boiler feeding, tank, vacuum,

designed for high pressure boiler feeding and also for mine sinking purposes. Engineering readers will at once notice a distinct advance in

the right direction by placing the steam chest and cylinder ports of the Attwood pump on the side of the cylinder instead of on the top as in previous designs, thus enabling the steam ports to drain the cylinder at every stroke of the piston, rendering the use of cylinder drain cocks quite unnecessary. Every operating engineer knows of the trouble caused by water accumulating in a pump cylinder when the steam ports are located on top of the cylinder necessitating the drain cocks to be left slightly open all the time to prevent water hammer. This condition becomes still more aggravated in a

FIG. 5.

FIG. 6.

vacuum pump operated by a governor when used on a steam heating system owing to the slow piston speed and occasional periods of rest. Condensation will accumulate in the steam line as well as in the steam cylinder.

Vacuum pumps on low pressures will frequently refuse to start off the governor under such conditions until the cylinder drain cocks are opened. Again pumps for mining purposes have long and tortuous steam lines which are not insulated and frequently have cold water dripping on them from the roof. Such conditions are the worst possible and produce the maximum amount of condensation and trouble for the en-

gineer. The cylinder and valve becomes water-logged, lubrication is washed away, rod and joint packings are ruined and cylinder heads and pistons are fre-

quently broken because the cushion is destroyed by the presence of water in the cylinder.

An examination of the drawings accompanying this article reveal two notable facts, viz.: 1st. The simplicity of the valve motion and its operation. 2nd. A complete automatic self-draining system accomplished by the disposition of steam chest, steam cylinder ports and pipe connections, as illustrated in Figs. 5 and 6.

It is apparent that cylinder drain cocks are superfluous because condensation through all the operations drains to the atmosphere by gravitation and the arrangements of steam ports permit the use of saturated steam without any risk to the cylinder head as already demonstrated by a series of daring experiments carried out under the worst conditions.

Figs. 8 and 9 show improved designs of a vertical outside packed ram pump which has the special feature of dispensing with one of the ram packing glands used on this type of pump, thus enabling an outside packed pump to occupy practically no more space than an inside packed pump of same length of stroke.

FIG. 8. FRONT ELEVATION OF OUTSIDE PACKED RAM PUMP.

FIG. 9. SIDE VIEW OF FIG. 8.

### CONSIDERATION OF ASSISTANTS

THERE are two principal ways for a manager and his assistant to work together. One kind of a manager works very hard himself and does not leave much of importance for his assistant to do. The other kind lets his assistant do all he can while he reserves his own time and thought chiefly for things the assistant cannot do—at least, cannot do so well. He puts responsibility on his assistant just as fast as the assistant shows his ability to take it.

The first manager retards his own growth and that of his assistant. He is always over-worked and has little or no time to think of new things. He is often doing work that should have been done several days before. His assistant either chafes under the restraint, or concludes that he is incompetent, and settles into a dull mediocrity.

The second manager has time and opportunity to grow, and gives his assistant room to grow also. The assistant feels his own strength, and loves his work. He shoulders the responsibility with eagerness, and the work goes merrily on. Ask yourself, which is best.

FIG. 7. HORIZONTAL, INSIDE PACKED, POT VALVE PUMP WITH EXTRA LONG STRETCHER AND PISTON ROD.

gineer. The cylinder and valve becomes water-logged, lubrication is washed away, rod and joint packings are ruined and cylinder heads and pistons are fre-

The saving in weight, friction, packing and space appeals to marine and stationary engineers alike, and the moving parts which are accessible without

The biggest number of starters on record for a bicycle race, 76 in all, were sent away over the Canadian National Exhibition course on one of its Athletic Days.

### MUNITIONS OUTPUT SHORTAGE—THE LABOR AND CONTRACT PRICE FEATURES

A STUDY of the descriptive article in another section of this issue, covering the machining department of a British National Shell plant should have the result of providing timely enlightenment to those—male and female, whose enthusiasm outpoints their intelligence in the matter of seeking to thrust on Canadian metal-working plant managements the onus of refusing to employ women munitions workers on either a lesser or greater scale, or at all. Among a number of things to be noted in this particular plant—which by the way is but a unit of a myriad so established enterprises, the fact of its bearing the qualification "National," has quite a good deal of significance for our patriotic citizens, and especially so for our equally patriotic, responsible Government.

#### Official Support Lacking

Catering to the spectacular has not been overlooked by our Government in this war-time, yet the erection of even a modest number of "National" munitions plants does not appear to have harmonized with the rest of the display. Has it been because the "National" would have overshadowed the individual achievement? Whatever the reason it has been wholly left to our metal-working plant administrations to work out our national salvation, and, when opportunity offered, to be well slammed as seekers after abnormal profits. It appears to be pretty well substantiated that the manufacture of brass cartridge cases is quite remunerative, yet as regards the plants so engaged, their number is a mere handful in the scope of our munitions production, and as a consequence they figure little—if included at all as contributories to the present munitions output shortage.

The munitions product in its main and detail part into which steel enters is what our manufacturers and the Imperial Munitions Board are exercised over meantime, although their views may be said to be widely divergent as to the cause or causes from which the falling off in production arises. It will be clearly evident from the British National Shell Plant description and illustrations that the general conditions for female operators are as nearly as possible ideal, and that therefore their substitution for men already enlisted and their being procured to take the place of still employed, but eligible men, become comparatively easy of accomplishment. To any

one familiar with our metal-working plants generally, the comparison between them and the British National Establishments is odious, for, right from the entrance gates in the case of the former, an atmosphere for "men only" makes its presence felt; nor do we expect other, for in their establishment and institution they were designed and laid out so.

#### Theoretical Displaces the Practical

Isn't it more or less a waste of time for the Munitions Board to keep "harping away on this female employment string," in view of what has been said, and taking account of the disabilities under which not only the women would labor, but all concerned in the plant management. Our manufacturers equipped their plants to handle both quality and quantity output of munitions, and received in the beginning, we believe, prices which enabled them to do so more or less profitably. A new situation has arisen, but in many respects similar to that which marked the institution of shell-making within our borders. Male labor is scarce through enlistments for overseas service, the output of munitions has materially decreased, our Government still continues to look on, and the Imperial Munitions Board invites manufacturers to save the situation by employing female labor, while apparently ignorant of plant conditions to make the latter possible. The Board cannot, we understand, establish "National" factories, and both it and our Government appear equally helpless in furnishing direct assistance in the matter of extending or rearranging plants whose managements are willing to employ female labor.

Why we ask should Canadian women be asked to take employment under conditions so much less inviting than their British sisters. Grievous fault was found with the Shell Committee because of its personnel being largely composed of men whose intimacy with engineering workshops was a very essential part of their every-day life. The readjustment has not, however, improved that feature. The situation is, we admit, a delicate one to adjust for, as National factories are remote possibilities, and grants to individual firms are much in the same category, there remains but an increased product price to enable the manufacture to make the necessary extensions to his plant to accommodate female labor. Just here, of course, a difficulty is still in evidence, for all need not and certainly all would not perhaps recognize female labor to be available, yet all would very probably call for the higher prices ruling on each particular munition detail.

#### Manufacturing Enthusiasm Chilled

In view of the foregoing we reiterate that the situation is a delicate one, but not however outside the pale of adjustment. In spite of the male labor shortage which is admittedly of considerable proportions, the manufacturers' enthusiasm as we stated a week ago has been chilled by the keenness of prices ruling, and while we are not prepared to say that more margin would eliminate the munitions output shortage, we think it would go quite a long way towards it. We are in any case quite certain that the present indifference to the employment of female labor would be less marked. The tendency to place contracts at the lowest possible prices, while praiseworthy, can be carried to extremes, and it would appear that with shell and shell part forgings of steel, brass parts, shell machining, and shell boxes, all more or less involved, prices ruling are a trifle keen. Experience proves that the speediest production is secured when manufacturers and operators have on the one hand the hope of profit and on the other the certainty of a fair rate of wages. It seems to us that it is possible to prevent the British people from being robbed, without alienating Canadian manufacturers from munition contracts, as appears to be the meantime situation.

# SELECTED MARKET QUOTATIONS

Prices Per Lb. Unless Otherwise Stated.

Pittsburgh following the placing of extensive contracts for large shells has given considerable impetus to buying both by manufacturers and merchants. Efforts are now being made to place contracts for the remainder of this year and the first half of next but producers are not over anxious to accept even at present prices. Pressure from foreign buyers of shell steel has finally forced producers to get down to business in spite of their desire to accommodate domestic consumers, however dilatory these may have been. Shell steel is now held at 3.75c to 4c per pound Pittsburgh. Structural shapes are quoted 2.50c to 2.60c, soft steel bars 2.50c to 2.60c, hoops 2.75c to 3.00c, bar iron 2.65c to 2.75c, all Pittsburgh. Semi-finished materials are quoted as follows f.o.b. Pittsburgh. Forging billets, \$65 to \$70; Bessemer billets, \$45 to \$46; open hearth billets, ditto; Bessemer and open hearth sheet bars being also quoted at this price. The demand for plates and sheets continues strong. Consumption of plates on the Pacific coast continues at a high rate while the efforts of foreign builders to secure supplies on this continent has contributed to the present high export prices obtainable. Shipyards on the eastern seaboard are already negotiating for material, while railroad companies are known to have absorbed large tonnages on rolling stock maintenance.

Tank plates are quoted 3.50c to 4.00c Pittsburgh, a few widths being quoted at 3.00c to 3.25c, with 3.50c for immediate delivery. Up to the present no figure has been mentioned as to the price of sheets for fourth quarter of this year, although some consumers are even now endeavoring to contract for next year shipments. The demand for black, blue annealed and galvanized sheets remains unchanged. Pittsburgh quotes blue annealed, Nos. 9 and 10 (base), 3.00c to 3.25c; Nos. 3 to 8, 2.95c to 3.25c; Nos. 15 and 16, 3.20c to 3.45c. Galvanized sheets, No. 28 (base), 4.25c to 4.50c; Nos. 10 and 11, 3.25c to 3.50c; Nos. 22 and 24, 3.80c to 4.05c. Cold-rolled box annealed, Nos. 9 to 10 (base), 3.00c to 3.25c; Nos. 15 and 16, 3.20c to 3.45c. Tin plate, \$6 per 100 lb. The demand for shapes for home consumption is comparatively quiet owing to continued high prices, 2.60c being asked for some shapes at Pittsburgh. Export demand still retains fair proportions.

**Metals**

Spelter has been an interesting member of the metal markets this week, export and other business having been placed covering business to the end of the year. Much interest attached to the announcement that Great Britain had reached an agreement with Australia whereby the former contracts to purchase 100,000 tons of zinc concentrates and 45,000 tons of spelter annually dur-

## The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

**Montreal, Aug. 19.**—Among the more interesting features of the week are the renewed activity in pig iron and the continued buying of shell steel by the belligerent powers. The latter has assumed a more desirable aspect in the eyes of some producers by reason of a substitution clause whereby the original form in which the material was ordered may be changed at the option of the purchaser, the balance being taken in sections such as structural shapes, plates, bars and other non-war purpose forms. Satisfactory crop reports continue to be received from the various grain districts with the usual stimulating result on business conditions generally. Business in machine tools and allied products shows signs of further

activity in the future but deliveries which are the chief basis of present business have suffered somewhat as a result of the renewed activity in export business from the States.

**Pig Iron**

Prices continue firm as a result of increased enquiry for both home and foreign consumption. Any prospects of future advances are the subject of close scrutiny by large consumers, although for the present a small amount of price shading has been done on early deliveries. Pittsburgh prices remain steady at \$21.95 for Bessemer, \$18.95 for basic, and \$19.45 for No. 2 foundry.

**Steel**

The recent advance in bars to 2.60c

ing the war and for ten years afterward. Something of this nature has been expected for some time in view of the announcement by Australia some time ago that the industry would never be again tainted with German influence. Copper, tin, and lead are quiet and firm, with a slight upward tendency during the week. Antimony has registered a 50 per cent. increase in a few days from the recent low price, largely as a result of the stoppage of sales by importers.

**Copper.**—Large sales are reported on an active market. No definite information has been obtained regarding the progress of large foreign orders under negotiation, and until this is disclosed the market will remain more or less exitable. London quotes spot standard at £111, futures at £108/10, and electrolytic at £127. New York reports that during the last few weeks home consumers have purchased up to possibly 150,000,000 pounds, despite the fact that large producers were considered to have sold up to the end of the year. Prime lake is quoted at \$31, electrolytic \$31, and casting \$30.

**Tin.**—The getting of permits for Straits tin continues to be difficult with a corresponding strength showing in Banca tin. Near futures at reasonable prices are obtained with difficulty. Spot tin is steady at \$28.25 to \$32.75 New York, and £169/5 spot, £170/5 futures, London. Local quotation 43c per lb.

**Spelter.**—General conditions continue to justify the recent strength shown by spelter. The galvanized sheet trade holds promise of more activity. More than half of Australia's annual output is booked for a term of years, and several large producers report contracts covering from 50 per cent. to 75 per cent. of their output for the balance of the year. Prices are firm at 14c per lb.

**Lead.**—Increasing strength has been shown during the week. Recent good sales by independent producers have prepared the market for an advance, which was promptly followed by the Trust. Local price 8½c per lb.

**Antimony.**—Great activity in antimony was a feature of the week, and the recent low level of \$10.50 has disappeared in the rapid advance. All of the metal offered is obtained from distant sources, which fact, along the increased demand for ammunition, points to higher prices for some time. The fact that only a few months ago antimony was almost three times its present price shows that a substantial jump is not impossible from the present price of 17c per pound.

**Aluminum.**—No change is noted in aluminum, present prices remaining firm at \$58 to \$60 for No. 1 Virgin, \$56 to \$58 for pure re-melt, and \$45 to \$47 for No. 12 alloy re-melt. Local price 68c.

#### Machine Tools and Supplies

Conditions are practically unchanged

so far as demand is concerned. Considerable business is promising, but majority of inquiries are not productive of immediate results. Deliveries have suffered somewhat, due to the recent recurrence of activity in certain branches in the States, but with the greatly increased production there, this condition is more or less temporary. Small tools and supplies continue in good demand. No great stock of supplies has been laid up by consumers, and orders are for immediate requirements only and correspondingly urgent.

#### Scrap

Dealers report very little activity, although prices are fairly well maintained. The renewed strength of pig iron is expected to improve matters, and conditions during the fall should be more satisfactory.

**Toronto, Ont., Aug. 22.**—The shortage of raw materials particularly, semi-finished steel, will doubtless be the most

#### CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion \$100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

important result of the heavy new demand for steel. The shortage will be reflected in prices and deliveries of practically all kinds of machinery both small and large. Until recently it was thought that the crest of the upward movement had been reached, but the new developments have changed the aspect of the situation and previous calculations have been upset. In addition, the scarcity of skilled labor will help to further complicate matters which have already reached an acute stage. The combined effect of these two causes will mean a further reduction in output at a time when maximum production is so much desired and in the case of munitions and war supplies, imperative.

#### Steel

Although there have been no price changes in this market except in wire nails since the recent new buying movement started in the States, it is very likely that an advance in some steel products may be made in October for the fourth quarter, if not before then. Apart from the demand for steel for munitions, business is above the average for this

month and is much better than for the corresponding period last year. Not only has domestic business improved but the steel companies continue to do a large export trade. In addition to its large output of shell steel, the Steel Company of Canada is making arrangements to take care of the increased demand for steel for other purposes. All signs point to a continuance of the present extraordinary activity in the steel trade for a considerable part of 1917. Prices of all steel products continue very firm, the plate situation being particularly strong owing to the heavy demand in the United States for ship and other plates, except car material. The boiler tube situation is unchanged, there being a continued heavy demand in the primary market for merchant and locomotive tubes. Prices of wrought iron pipe are firm and unchanged, particularly black pipe although galvanized material has recovered from its recent weakness.

The situation in the sheet market continues firm and unchanged. The demand for black and blue annealed sheets remains steady although prices are somewhat irregular. An advance of \$2.00 per ton on sheet bars has stiffened the market for black sheets and may result in higher prices, as sheet bars are now considerably higher than at the time when black sheets were last advanced. Prices of galvanized sheets are firmer but the demand is comparatively light at the present time and the output of the mills is much below normal.

The greatest activity again characterizes the steel trade in the United States since the new buying movement started. Domestic consumers who have been for some time waiting for price recessions will now have to pay higher instead of lower prices for their steel. As a result of the new demand a more pronounced scarcity of semi-finished steel has developed which will affect the situation to a greater degree than higher prices. Prices of Bessemer billets and open-hearth sheet bars have advanced \$2.00 a ton and are now quoted at \$45.00 and \$47.00 per ton respectively f.o.b. Pittsburgh. Steel bars are now quoted at 2.60c; plates 3.50c and shapes 2.50c f.o.b. Pittsburgh.

#### Pig Iron

The pig iron market is marking time and the situation is unchanged. The demand for steel-making grades of pig iron is as insistent as ever, but foundry iron is quiet. Quotations are unchanged.

#### Machine Tools

The situation in the machine tool market is unchanged, business being almost entirely with munitions plants. A steady demand continues for large swing lathes, while tool maker's equipment is in fair demand. Deliveries are show-

ing some improvement but no price revisions have been made recently although advances are looked for on some lines of machine tools.

### Supplies

The demand for machine shop supplies continues brisk with prices very firm, particularly for iron, steel and brass goods. The shortage of raw materials is adversely affecting the situation, causing a scarcity of some supplies. White lead has declined 50c per 100 lbs., and is now quoted at \$13.45 per 100 lbs. in ton lots.

### Metals

The metal markets have undergone a decided improvement during the week with an upward trend in prices. The stronger tone is a result of heavier demand which is particularly evident in copper and spelter. Business locally has improved and is good considering the time of the year.

**Copper.**—The large buying of copper for the Allies and enquiries for additional large amounts of metal has resulted in a strong market and higher prices. It has also had the effect of forcing domestic consumers into the market and an important selling movement is now in progress. Sales of copper for delivery during practically the next twelve months have been made and indications point to a high level of prices for that period. Copper has advanced  $\frac{1}{2}$  cent locally and is now quoted at 29 $\frac{1}{2}$  cents per pound.

**Tin.**—An improved undertone in the tin market due to heavier demand has had the effect of advancing prices. Tin is now quoted at 44c per pound.

**Spelter.**—The recent declines in spelter would appear to have stimulated business as the demand has considerably improved during the week. Galvanizers are buying more spelter and brass mills are taking more metal. Local quotations are higher at 14c per pound.

**Lead.**—The position of lead is strong and the price has advanced, the Trust now quoting 6.25c, New York with independents at the same level. The market at present is rather slow but a much improved demand is anticipated. Lead is now quoted at 8 $\frac{1}{2}$ c per pound.

**Antimony.**—The demand is active with the market higher and excited. The price has advanced and indications point to still higher prices. Antimony has advanced 1c and is quoted locally at 17c per pound.

**Aluminum.**—The market is quiet but firm with quotations unchanged at 68c per pound.

**Solder.**—Quotations are firmer but unchanged. Guaranteed is quoted at 27 $\frac{1}{2}$ c and strictly at 25 $\frac{1}{2}$ c per pound.

## Trade Gossip

**Quebec Bridge.**—It is expected that between September 14 and 16 the great centre span of the Quebec Bridge will be floated into position. This will pave the way for the opening of the structure early next year.

**Paper Industry Develops.**—It has been stated on good authority that there are in course of erection in the Dominion of Canada paper mills and increased machinery sufficient to make at least 750 tons a day of extra product.

**Flaws In Steel Rails.**—President A. H. Smith, of the New York Central, has announced that Dr. Plimmon H. Dudley, head of the railroad staff of scientists, has discovered the cause and an absolute remedy for hidden flaws in steel rails.

**The Jenckes Machine Co.,** of Sherbrooke, Que., have been awarded contracts for steel and cast iron columns by the Canadian Cotton Mills for a factory extension, and by the Sherbrooke Railway & Power Co. for a transformer station.

**The Tivani Steel Co.,** Belleville, Ont., which has been experimenting for some time on an electric smelting process for the direct reduction of refractory ores, is now about to engage on a commercial scale in the manufacture of high-speed molybdenum steel. A three-phase electric furnace is used.

**The Standard Ideal Co.** plant, Port Hope, Ont., has been sold to L. M. Wood, of Toronto, president of the Standard Chemical Co. of Toronto, and associates, among whom are W. D. Ross, financier. The new company will take possession at once, and will carry on the present line of business. It is understood that the name of the concern will be changed to the Port Hope Sanitary Mfg. Co.

**French Steel Output.**—Steel production in France during the second year of the war was double that of the first year, it was shown by statistics submitted at a general meeting of the French Steel Association recently. Eighty per cent. of the pig iron and 70 per cent. of the steel prior to the war was produced in the part of France now invaded.

**The Manitoba Steel Foundries, McArthur Building,** Winnipeg, states that its new foundry is nearing completion, and that one furnace will probably be in operation September 1. The company will make electric steel, both in the form of castings and ingots for rolling, and when in full operation will have an annual capacity of 8,000 to 10,000 tons. A. M. Tirbutt is secretary and treasurer.

**Copper Output Up to 50 Per Cent.**—Twenty leading copper companies operating in the United States, Canada and South America produced approximately 895,000,000 pounds of copper in the first half of 1916, an increase of 299,000,000 pounds, or 50 per cent., over the corresponding period of last year. Of these, the Anaconda made the largest individual increase—52,300,000 pounds more than a year ago.

**Thanks Canadian Firm.**—The official Press Bureau, London, England, recently gave out this statement: The Canadian Cartridge Co., at Hamilton, Ont., having completed a large contract for cartridge cases, handed the Imperial Munitions Board of Canada \$758,248, this sum being the difference between the contract price and the cost of the materials and the manufacture. Minister of Munitions Montague thanked the company for its patriotism.

**Sulphuric Acid Plant.**—The new sulphuric acid plant of the Consolidated Mining & Smelting Co., at Trail, B.C., is now in operation, being the only plant of its kind in B.C. The acid is recovered from the sulphur fumes from the furnaces, previously allowed to go to waste. The output is about ten tons daily, of which five tons is required for use in the company's own works, the balance being readily sold on the market, which at the present time is poorly supplied, prices having risen considerably since the war.

**Windsor, Ont.**—Charles A. Bradley, manager of the Windsor branch of Remington Arms Co., is authority for the statement that negotiations are in progress for the sale of the company's Windsor property to a syndicate composed of New York capitalists. Mr. Bradley said that a change in the policy made by the Remington parent company intended to centralize the business at Bridgeport, Conn., is the reason why the Windsor plant is on the market. Since the Remington firm located here four years ago more than \$40,000 has been spent in additions to the factory. Over 150 men and girls are employed.

**Australian Spelter Contracts.**—It is reported from London that an agreement has been reached between Great Britain and Australia, under which Great Britain contracts to purchase 100,000 tons of zinc concentrates, and 45,000 tons of spelter annually from Australia during the period of war, and for ten years afterwards. The effect of the agreement will be to ensure the transfer of the smelting industry from Germany to British hands. The amount exceeds \$25,000,000, covering more than half of Australia's annual report output. The remainder of the output is expected to be taken over by France and Belgium.

**Safety of Explosive Plants.**—It is announced from Ottawa that an Order-in-Council, under the War Measures Act, 1914, in order to make greater provision for safety in explosives factories, provides that every person who takes or attempts to take or assists in taking any matches into any explosives factory or into any building, enclosure or place wherein the manufacture of explosives is being carried on, or has matches in his possession while in any such factory, building, enclosure or place, is liable to a fine not exceeding \$100 or to imprisonment for any term not exceeding six months, or to both fine and imprisonment.

**Tungsten in B.C.**—Considerable interest attaches to a discovery of tungsten ore on the Mud Creek claims of Wm. Thompson and Barney Halloran and while the amount of this valuable mineral is not yet sufficient to warrant working the property for the tungsten values alone, the fact that this mineral exists has added a new incentive to prospecting and mine development in this district. Advice from the Mines

Department at Ottawa are to the effect that tungsten ore carrying 60 to 65 per cent. of the mineral is worth \$4500 per ton, and that the ore may be marketed through the Canadian Munitions Resources Commission.

**Australian Parliament Bldgs.**—Canadian architects are to be given the opportunity of competing for the furnishing of plans for the construction of the new Australian Parliament buildings. Their construction was planned before the war, but was allowed to lapse at the outbreak of hostilities. The following cablegram, however, has been received by the Prime Minister from the Acting Premier of Australia: "With reference to my telegram of September 25, 1914, in the matter of both Houses of Parliament, the architectural competition for the Federal Capitol, issued 1914, has been resumed. Designs are receivable to January 31, 1917. Would appreciate publication."

**Tinplate Industry to be Revolutionized.**—It is reported from Cardiff, Wales that the tinplate industry is about to undergo

a revolutionizing process owing to the introduction of a new method of tinning and preparing plates for tinning, according to an announcement made by the Mellingriffith Tinplate Works in South Wales. The process now said to be in successful operation dispenses with the necessity of white pickling, and the white annealed plates, after being separated, are, without handling, taken up by machinery and picked, washed, turned, cleaned and piled. It is asserted that the new method increases the production of tinplates in the proportion of more than two to one as compared with the ordinary process.

**Government Sells C.G.S. Montmagny.**—The Canadian Government steamer Montmagny, which has been beneath the waters of the St. Lawrence, near the Island of Orleans, for almost a year, has been sold by public tender to the St. Charles Navigation Co., of Quebec, for \$25,000. The vessel originally cost over \$100,000. A contract was some time ago given to the Levis Wrecking Co. to raise the Montmagny, but they were unsuccessful.

## CANADIAN COMMERCIAL INTELLIGENCE SERVICE

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

# INDUSTRIAL <sup>A N D</sup> CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

## Engineering

**Sarnia, Ont.**—The Sarnia Gas Co. is making considerable extensions to its gas mains.

**Chatham, Ont.**—The directors of the Gray-Dort Motor Co. have decided to extend their plant here.

**Toronto, Ont.**—The Bawden Machine Co., will build a two storey addition to their factory at a cost of \$2,000.

**Niagara Falls, Ont.**—The Pollard Mfg. Co., will shortly begin the construction of a foundry to cost about \$40,000.

**Toronto, Ont.**—John T. Hepburn, Ltd., 18 Van Horne street, will erect a one-storey frame galvanized iron addition to machine shop at a cost of \$3,000.

**Niagara Falls, Ont.**—Plans have been prepared for the erection of a \$200,000 addition to the Lincoln Paper Mills at Merritton. The addition will consist of a sulphite plant.

**Hamilton, Ont.**—The Brown-Boggs Co. has awarded a contract for the rebuilding of their plant to H. G. Christman & Co., of Hamilton. The cost will be about \$15,000.

**Joliette, Que.**—The Joliette Steel Co., whose head office is in Montreal, is in the market for a new or second-hand

three to five-ton suspension scale for weighing steel castings.

**Port Arthur, Ont.**—The Canadian Northern Railway will shortly proceed with the construction of a machine shop here. The general contract has been let to J. Brown of Winnipeg.

**Toronto, Ont.**—The Toronto Suburban Electric Railway are installing a new generator supplied by the Canadian Westinghouse Co., of Hamilton, in the power house on the Weston Road.

**Port Colborne, Ont.**—It is understood that the International Nickel Co. will establish a nickel refining plant here. Options have been secured on a site and other preliminary work has been started.

**Cornwall, Ont.**—Additional machinery, will be installed by the Toronto Paper Mfg. Co., which will bring the capacity of the plant up to 30 tons per day. R. S. Waldie is president and W. Wallace is manager.

**Toronto, Ont.**—The Canadian Hanson and Van Winkle Co., will build an extension to their foundry to cost \$7,000.

**Ottawa, Ont.**—The construction of a civic workshop is contemplated by the City Council. A. F. Macallum is city engineer.

**Goderich, Ont.**—The Doty Foundry, which has been closed for some time past, will in the near future be re-

opened, and everything will again be in full swing. An arrangement has been reached by W. J. Thorold and the local Town Council, and the former will continue the operation of the plant.

**Kingston, Ont.**—Lewis F. Houpt, of Buffalo, has purchased the Thomson paper mills at Newburgh, and has organized a company. He is having the building repaired and machinery installed. The concern will manufacture all high-grade bond papers. Mr. Houpt is now president of the George Irish Paper Co., Buffalo, and the Monarch Paper Co., Toronto.

**Toronto, Ont.**—The William Davies Co. have had plans prepared for the erection of three buildings of flat slab concrete construction on Front Street east. The company will erect an abattoir and tank house, five and three storeys respectively, to cost \$60,000; a cold storage building, six storeys, to cost \$100,000, and stock pens, seven storeys, to cost \$40,000. The total expenditure on the buildings will be \$200,000.

**Toronto, Ont.**—The British-Canadian Refining Co. have been granted a lease by the Ontario Government for the development of power on the Wahnapiatae River, to be used in connection with their proposed smelting works near Sudbury. The Hon. G. Howard Ferguson, who made the announcement recently, declared that four or five million dollars

## Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

**BRAZIL**  
Bahia, British Consul.  
Rio de Janeiro, British Consul General.  
**CHILE**  
Valparaiso, British Consul General.  
**COLOMBIA**  
Bagota, British Consul General.  
**ECUADOR**  
Quito, British Consul General.  
**EGYPT**  
Alexandria, British Consul General.  
**FRANCE**  
Havre, British Consul General.  
Marseilles, British Consul General.  
**INDIA**  
Calcutta, Director General of Commercial Intelligence.

**ITALY**  
Genoa, British Consul General.  
Milan, British Consul.  
**MEXICO**  
Mexico, British Consul General.  
**NETHERLANDS**  
Amsterdam, British Consul.  
**PANAMA**  
Colon, British Consul.  
Panama, British Vice-Consul.  
**PERU**  
Lima, British Vice-Consul.  
**PORTUGAL**  
Lisbon, British Consul.

**RUSSIA**  
Moscow, British Consul General.  
Petrograd, British Consul.  
Vladivostok, British Consul.  
Odessa, British Consul General.  
**SPAIN**  
Barcelona, British Consul General.  
Madrid, British Consul.  
**SWEDEN**  
Stockholm, British Consul.  
**SWITZERLAND**  
Geneva, British Consul.  
**URUGUAY**  
Monte Video, British Vice-Consul.  
**VENEZUELA**  
Caracas, British Vice-Consul.

## LeBlond 14" Quick Change Engine Lathe

Single or Double Friction  
Back Geared

## LeBlond 24" Standard Engine Lathe

Single or Double Friction Back Geared

LeBlond 14-in. Q.C. Engine Lathe as the keystone of your tool-room equipment will at once stamp that department as "efficient." It has a 4-step cone for a 2-in. belt and graduates from  $4\frac{3}{4}$ -in. to  $10\frac{3}{4}$ -in. dia., compound rest, follow rest, steady rest, swings over shears  $15\frac{1}{4}$ -in., swings over carriage  $9\frac{1}{2}$ -in., distance between centres 3-ft., weight 1725 lbs. By these few specifications and a study of the upper illustration you will see that for quality, strength, rigidity and efficiency this machine would fit exactly into your requirements. Send for full particulars and specifications.

The LeBlond 24-in. Standard Engine Lathe stands pre-eminent among the many general purpose lathes manufactured, in quality, workmanship and general design. A glance at the illustration will at once impress this on you. It swings over shears  $24\frac{1}{2}$ -in., swings over carriage 16-in., distance between centres 5-ft., 3-step cone 4-in. x 10-in.,  $12\frac{1}{4}$ -in.— $14\frac{1}{2}$ -in. dia., hole in sp.  $1\frac{1}{2}$ -in., comp., steady and follow rests, weight 5700 lbs. It's a thoroughbred, a mere glance at the illustration will tell you that. But looks are not everything, if you will write us we will give you such specifications and particulars that will convince you of its undoubted leadership quality.

will be invested in the property, but he is not ready yet to announce the terms of the lease.

**Dundas, Ont.**—The John Bertram & Sons Co. is calling tenders for the erection of a pattern shop.

**Montreal, Que.**—William Hood & Son, 10 Richmond Square, are in the market for a 10 to 15-h.p. electric motor, a heavy Bliss trimming or punching press, a power hack saw, and a 2,000-pound drop forge hammer.

## Municipal

**Nokomis, Sask.**—It is proposed to install an electric light and power plant here.

**Almonte, Ont.**—The Town Council will build a Hydro-Electric plant to cost \$18,000.

**Halifax, N.S.**—The City Council contemplate the construction of an abattoir at an approximate cost of \$25,000.

**London, Ont.**—An extension is being made to the sewage disposal plant at an estimate cost of \$40,000. The engineers are Chipman & Power, Mail Building, Toronto.

**Richmond Hill, Ont.**—The Village Council contemplate installing a water-works system at a cost estimated at \$30,000. James, London and Hertzberg of Toronto are the engineers.

**Montreal, Que.**—City engineer Mercier has recommended the purchase of ten auto-flushers for the road department. These machines cost about \$9,000 each.

**Dunnville, Ont.**—The Town Council will submit a by-law to the ratepayers for authority to borrow \$53,000 for the purpose of installing Hydro-electric light and power, and to buy out the plant of the existing light company.

**Lethbridge, Alta.**—The following tenders have been submitted for the proposed filtration plant; New York Continental Jewell Filtration Co., of New York, \$92,000; Roberts Filter Manufacturing Co., Darby, Pa., \$95,000; Western Canada Foundry & Supply Co., \$111,857.

**North Bay, Ont.**—A by-law will be submitted to the citizens in the course of a few weeks to guarantee the bonds of the Queen Hat Mfg. Co. of Toronto, and give a free site. The company will locate at North Bay if the by-law passes. The town secures a first mortgage on machinery.

**Toronto, Ont.**—The railway viaduct on the Esplanade may be delayed until after the war on account of the finan-

cial situation; but the Union Station will be completed. The city is financially interested in the construction of the viaduct, and it, as well as the railways, will find it difficult to finance large undertakings for some time.

## General Industrial

**Hamilton, Ont.**—The Mercury Mills, Ltd., are building a factory here.

**Ottawa, Ont.**—The National Mfg., will build an extension to their factory to cost about \$4,000.

**Toronto, Ont.**—The Willard Co., contemplate building an extension to their chocolate factory.

**Burford, Ont.**—The Canadian Milk Products Co., Toronto, propose erecting a factory here to cost about \$100,000.

**Toronto, Ont.**—The William Wrigley Co., will build a large addition to their chewing gum factory on Carlow Ave.

**Toronto, Ont.**—Adams Brothers' Har-ness Mfg. Co. will erect a factory on King Street West. Estimated cost, \$75,000.

**Pembroke, Ont.**—Damage to the extent of \$10,000 was done by fire in the factory of the Pembroke Woollen Mill's Co. on August 15.

**London, Ont.**—Plans are being prepared for an addition to a factory for J. R. Shuttleworth, hat manufacturers. Estimated cost, \$10,000.

**London, Ont.**—plans are being prepared for an addition to the premises of the Canada Cereal Mills Co. Estimated cost, \$10,000. Manager, J. A. Barnard.

**Sarnia, Ont.**—William P. Fitzsimons, Commissioner of Industries for the Grand Trunk, has notified A. G. Lashinger, at Point Edward, that for the present no action will be taken on the part of the dye industry to locate in Western Ontario. Negotiations, however, will be renewed at a later date, when it is hoped to make final plans for the locating of the plant at this point.

## Electrical

**Renfrew, Ont.**—A Hydro-Electric by-law will be submitted to the ratepayers on September 2.

**Dutton, Ont.**—A proposal is under way for the extension of the hydro line from Dutton to Wallacetown.

**Dunnville, Ont.**—The Dunnville Electric Light Co. have offered to sell out their plant to the Hydro for \$30,000.

## Contracts Awarded

**St. John, N.B.**—Fire on August 11 damaged the Consumers' Sack Co.'s factory to the extent of \$7,000, which is covered by insurance.

**Brockville, Ont.**—T. J. Davidson has received the contract for the erection of a large addition to the premises of the Canadian Briscoe Motor Car Co.

**Oshawa, Ont.**—J. D. Young & Son, Toronto, has received the general contract for three buildings for the Chevrolet Motor Co. of Canada, at Oshawa, Ont.

**Walkerville, Ont.**—The Canadian Bridge Co. has been awarded the contract for the steel girder bridge over the Nelson River at Kettle Rapids, Man., for the Hudson Bay Railway, at a cost of \$325,000.

**Toronto, Ont.**—The Board of Control has granted contracts for seven motor fire appliances, valued at \$46,103. Hugh Cameron & Co. got the contract for the tractor at \$5900 and also the contract for the ladder and truck at \$8500. The contract for the combination salvage and chemical wagon was awarded to the Dominion Automobile Co. at \$4750. The Cameron concern also got the business for one commercial truck at \$4200 and a portion of the chemical wagon order.

## Personal

**Sir George Foster**, Minister of Trade and Commerce, has arrived at Montreal, having returned from England on the steamship Missanabie.

**C. W. Knighton**, general manager of the Canadian Hart Accumulator Co., of St. Johns, P.Q., has opened an office at 701 Merchants Bank Building, Winnipeg.

**A. C. Towne** has resigned his position with the Canadian Johns-Manville Co., Montreal, to take charge of the engineering department of the Electrical Equipment Co., Montreal.

## Tenders

**Toronto, Ont.**—Tenders will be received up to August 29, for the supply and delivery of 36-inch cast iron special castings. Specifications may be obtained at the Works Department, Room 12, City Hall.

**Toronto, Ont.**—Tenders for extension to Dunearn Street sub-station and addressed to Chairman, Toronto Electric Commissioners, will be received until August 30. Plans, specifications and form of tender may be obtained at the

## Marine

**C. S. L. New Freighter.**—Announcement is made in Detroit, Mich., that a new six hundred foot steamer being brought out for the Canada Steamship Lines, at the Superior yard of the American Shipbuilding Co., will be named after Sir Trevor Dawson, managing director of Vicker's, London. The boat is expected to go into commission some time next month.

**Vancouver Harbor Dues.**—Vessels using Vancouver harbor are to pay a tax of three cents a registered ton on and after August 1, according to notice from Ottawa. The harbor commissioners had this clause in their original by-laws together with other tariffs and license fees. Owing to the strong opposition engendered the tax was suspended during the war, but now the commissioners have succeeded in getting an Order-in-Council through for the imposition of the three cents tonnage tax. However, all the other tariffs and licenses are cancelled and the three cents tax is the only one. Ships will not be required to pay on more than five entries in a year. Shipping men do not regard the tax as excessive.

**S. S. Saronic Total Loss.**—Manager Gildersleeve, of the Northern Navigation Co., received that the wooden steamer Saronic had burned to the water's edge on the shore of Cockburn Island, Georgian Bay, where she was beached by her skipper, Capt. J. D. Montgomery, when she broke into flames amidships on Lake Huron early Sunday Morning. The crew of 21 men landed on this bleak shore in lifeboats, and made their way to Thessalon, where they were provided for. The Saronic was built at Sarnia in 1882, and was 252 feet in length. She was formerly the United Empire, and was in the passenger service until the 1914 season. On the present trip she was taking a cargo of grain to Port Nichol. She had no wireless, which caused the late report of the accident.

## KEYSEATER

for Milling Internal  
Keyseats

This tool is an attachment  
for the drilling machine,  
and is regularly made with  
straight shank for gripping  
in the drill chuck; taper  
shank can be had if desired.  
The tool is fitted with a  
high-speed steel rotary cut-  
ter for milling internal key-  
seats in one cut. To com-  
plete a keyseat it is only  
required to pass the tool  
through the hole just once.  
Innumerable inexpensive  
eccentric bushings are sup-  
plied whereby the tool may  
be bushed to meet any  
diameter above its own.

## Saving or Wasting?

The manner in which you handle the drinking water problem in your plant may seem to be a small matter to you—but investigate. The results will be surprising.

The old-time faucet is costly. Running hour after hour, day after day, its ceaseless flow is costing you money, yet without any better service.

### Puro Saves 35%

A Puro Sanitary Drinking Fountain will cut that water bill 35%. We can prove that it has done that for others.

It will give every employee a safe, saner draught of bubbling water free from the contamination of the common drinking cup.

In a word, it is the only sanitary Drinking Fountain that is really safe, sanitary, simple, automatic in control, and easy to attach.

## Staff Article

WHEN the production of munitions was first considered by our Canadian manufacturers during the early stages of the war, many of those experienced in metal working industries, were dubious of the success of the venture. However, time and perseverance has shown that this country

success has been achieved by those, who up to the time of shell making, had been engaged in an entirely different line of activity. The plant from which the following material was secured, had previously been, and in fact still is, largely engaged in general construction work; but the need of munitions was so urgent that the firm decided to equip a portion of its plant for the purpose of aiding in the good cause. The result of the initial undertaking proved so success-

TYPICAL PLANT LAYOUT FOR THE PRODUCTION OF 4.5 IN., 5 IN. AND 6 IN. HIGH EXPLOSIVE SHELLS.

ful that the entire plant is now equipped for the manufacture of high explosive shells. A brief description of the sequence of production operations on the 6 inch shells is here given.

forging will more closely conform to the desired specifications.

#### Heating and Forging the Shells

The forging department of this plant is equipped with all the necessary

is mixed with air at a pressure of 8 ounces.

When the billets have attained the desired heat, they are removed from the fire chamber by means of a long pair of tongs, which are supported by a chain hanging from a rail above the front of the furnace. This rail is arranged so that the shell in its passage to the press passes over a steel plate upon which the billet is dropped; this allows of the scale being removed from the surface before the piece is placed in the die. The removal of this scale is an important factor in the making of a good shell forging, as the adherence of scale, especially in uneven patches not only injures the dies, but prevents the steel from drawing uniformly when the punch is being forced into the metal, often resulting in a forging with eccentric walls. When the billet is dropped on to the plate, an operator quickly removes the hard scale with suitable scrapers; and while every particle is not taken off, care is usually exercised to have the surface as clean as possible.

Very little time is taken in this operation. The billet is next picked up by another workman with a pair of tongs and dropped into the die, which is made of vanadium steel, as are also the piercing punches. Before the forging of each shell, the punches and dies are cooled by means of running water, and all scale is blown from the die chamber by a blast of compressed air. The die is lubricated between each operation by swabbing the interior with a mixture of oil and graphite; and after the billet is placed in the die, a small quantity of coal dust

FIG. 1. MATHEWS GRAVITY CARRIER AT LEFT FOREGROUND WITH HEATING FURNACES AND FORGING PRESSES IN REAR.

#### Receiving the Billets

Two methods of producing the rough billets are now being used; that of casting an ingot in a metal mould, and the other of rolling a bar to the desired dimensions from a forged ingot. In the case of the former, sufficient molten metal is used in each ingot to insure a good sound billet after the crop end has been removed, which in the majority of cases amounts to about 20 per cent. of the total length of the cast ingot. When using stock from the forged bar, the rough portion at the end of the bar is first cut off, and then the billets of a length suitable for the shell forging.

This plant, not being equipped with the necessary facilities for producing the rough billets, receives them from outside sources, and is using stock derived from both the above processes. The billets arrive by teams and also by rail, being stored in separate piles, in relation to their respective heat numbers. To meet the requirements of the Munitions Board specifications, and at the same time maintain a high quality of product, it is essential that every furnace heat be kept separate, as it progresses through the various operations, to the finished shell. Owing to the experience of the past two years, and the increased facilities of production, the losses due to the variation in the physical properties of the different heats, have been greatly reduced. As every shell is stamped, indicating the heat and carbon content, the heating for the forging operation can be so adjusted that the nature of the steel in the finished shell

furnaces, presses and auxiliary machinery for the production of 4.5 and 6 inch high explosive shells. Two single and two double chamber Mechanical Engineering Co., furnaces are used for heating the smaller billets; while two continuous furnaces of the same make are used for the 6 inch billets. The approximate time required to heat the 4.5 in. billets to the desired temperature of about 2,300 degrees F., is roughly one

FIG. 2. JOHNSTON & JENNINGS SPECIAL PURPOSE LATHES FOR ROUGH TURNING 6 IN. SHELLS.

hour, and to heat the 6 inch billets to a corresponding temperature requires nearly  $1\frac{3}{4}$  hours. The crude oil used for heating the furnace, is under a pressure of 30 pounds per square inch, and

is thrown on the upper surface before the punch descends. This not only lubricates the punch while the shell is being drawn, but the gas generated at the nose of the punch aids in its removal after

the drawing operation is completed. If, however, the shell shows any tendency to cling to the punch when the ram ascends, provision is made whereby a block can be inserted in a suitable slide at the top of the die holder and the shell stripped from the punch.

Three 350-ton hydraulic presses, built by the Southwark Foundry & Machine Co., are operating continuously on the

FIG. 4. CHUCK EXTENSION PIECE ON BULLARD SINGLE PURPOSE LATHE FOR INSIDE BORE MACHINING.

6-inch shells, each with an approximate capacity of 30 to 35 an hour. These presses receive their power from two Southwark accumulators, one having a piston 24 inches in diameter and a stroke of 12 feet, with 315 tons of iron ore ballast, and the other a piston of 15 inches diameter, a stroke of 15 feet, loaded with 120 tons of iron ore. The accumulators are supplied by two Deans of Holyoke, and one Dean of Indianapolis hydraulic pumps. The two former are belt-driven, one from a 200 h.p. Allis Chalmers-Bullock Co. motor, and the other from a 200 h.p. Canadian General Electric Co. motor. The Dean pump is direct coupled to a 200 h.p. Triumph motor.

After the shells have been forged,

FIG. 3. CINCINNATI PULLEY LATHES ROUGH TURNING 6 IN. SHELLS.

they are removed from the die and placed upon a Mathews gravity carrier and transferred to another department. An idea of this installation can be gath-

ered from Fig. 1, which shows the gravity carrier in the foreground and the furnaces in the rear. The elevating portion of this conveying system is mechanically operated by means of a one h.p.

FIG. 5. BORING AND THREADING NOSE AND FINISH TURNING 6 IN. SHELL BODY.

motor, located on the structural steel column above the conveyor. When the shell reaches the top of the incline, it drops on to the rollers, and is subsequently transferred to any desired location in the same or an adjacent department.

#### Machining the Shells

Before the machining of the shells is proceeded with, the rough forgings are carefully examined by competent inspectors for visible defects. Every shell is subjected to various gauging operations, such as overall length, base thickness, concentricity of walls, etc., to avoid any

one side and gives an extra rough boring operation before being rough turned. Experience, however, has almost eliminated this feature, and, with few exceptions, the forgings produced in this

plant can be successfully machined without much loss from the forging process.

#### Cutting to Length and Rough Turning

To prepare the shells for the actual machine operations, it is first necessary to cut the surplus metal from either end of the rough forging. To avoid any unnecessary work on the interior of the shell, the preliminary gauging for the roughing operations is always made from the inside surfaces. When the open end has been cut to length, the base is roughed off, both these operations being accomplished in a number of Hall cutting-off machines. The centre in the base is also located in relation to the rough interior of the forging. This is advisable, for economic production, as it is much easier to remove the uneven metal from the outside surface of the shell. When the cut is irregular during the boring

FIG. 6. PROFILE FORMING ATTACHMENT.

operation, much additional wear and tear is placed upon both the tools and containing turret or operating mechanism. Several engine lathes fitted with three-point expanding arbors are used for centering the base of the shells. Two methods of producing the 6-inch shells are being employed in this plant—that of the steel nose piece (screwed in), and also the solid closed-in nose; the first being gradually superseded by the latter, however. The former method is adopted

defective shells reaching the machining department. When shells are discovered to have eccentric walls, and yet within the passable limits, they are placed to

FIG. 7. LYALL LATHES INSIDE PROFILING 6 IN. SHELLS.

when shells are found to be too short for the hot nosing process.

Several makes of lathes, including Wickes, McDougall, Johnston & Jennings, Canadian Fairbanks-Morse, etc., are working on the rough turning operation, the mean average output being approximately six shells per hour on the short shells, and slightly less on the hot nosed shells. In Fig. 2 is shown a row of Johnston & Jennings special purpose lathes at work on the rough turning operation. It will be noticed that small air hoists are provided to facilitate the handling of the shells to and from the lathe. One of these hoists is supplied to every two lathes, a rail running the length of the two machines. Fig. 3 shows a group of Cincinnati pulley lathes on the roughing operation. These machines are fitted with three cutting tools, each mounted on a separate carriage, so that two can be operating on the outside diameter while the third is used for facing off the base. The duty required is, however, so great that the production is no

FIG. 8. GROOVING AND WAVING 6 IN. SHELLS.

FIG. 10. SHELL FORGING STORAGE YARD.

larger than that of the single tool machine, as the feeds must necessarily be reduced; the only advantage is that the base can be faced off at the same setting.

#### Boring and Nosing the Shell

With the solid nose, the boring operation is somewhat longer, but the necessity of the thread for the other method (that of the removable socket) is eliminated. The cycle of operations when boring are similar to those of the smaller shells; that is, roughing the bore and mouth of shell, roughing out base contour and finishing open end, finishing bore and base profile. Upwards of thirty Bullard single purpose lathes are at work on this operation. These machines are all fitted with chuck extensions, similar to that shown in Fig. 4. These pieces are cored out, as shown, to eliminate weight and yet provide a good rigid support for the shell, when the tools are in operation.

The shells are now ready for hot nosing. Four Mechanical Engineering Co. nosing furnaces are provided for heating the mouth of the shell, this being inserted into the holes in the front of the furnace and exposed to the heat for a distance of between three and four inches. The temperature required is about 1,700 degrees F., and should be as uniform as possible to give the best results and to avoid undue wear upon the nosing die. It may be interesting to note that the water cooled chamber, through which the shells are placed, is made from two pieces of channel iron, the holes being cut and the entire jacket constructed by the oxy-acetylene process. This has been found to be a great improvement over the cast iron water jacket previously used. Four Perrin presses are being operated on the nosing process. Proper heating is the chief factor in the nosing

operation, and, to maintain the highest degree of efficiency, it is necessary to have a reliable man on the furnace, as an inexperienced operator may be the cause of an extra high percentage of rejected shells. If the shell is heated too far down, there is a possibility that the body of the shell below the profile will be distorted, often resulting in a short shell. On the other hand, too low a heat will cause excessive pressure to come upon the die, which may crack or break the latter.

#### Bore Nose and Finish Turn

After the shells are nosed, they are inspected for overall length and mouth opening. They next commence to receive the finished machine work. Each shell is placed in a special chuck for operations on the inside of the nose, that is, boring to a diameter of 1.9 inches, cutting a small recess 1.2 inches from the face of the shell, reaming and facing, tapping with a 14 thread Murchy collapsible tap, and finishing the face of the nose. The threaded portion is then sized with a hand tap. A driving plug is afterwards screwed into the nose, and the shell placed between the centers of an engine lathe, preparatory to finishing the outside diameter and nose profile. A view of this operation is shown in Fig. 5. The device used to obtain the desired contour of the nose

carriage, the tool being set in the desired position to form the proper shape of the nose. An auxiliary tool slide is

work. A view of one of the Lyall lathes is shown in Fig. 7, operating on the inside of the nose. Before proceed-

FIG. 11. GENERAL VIEW IN SHELL MACHINING DEPARTMENT.

fitted to the carriage for the purpose of turning the parallel portion of the shell. This extra head is, however, not always used; the single tool being often used to accomplish the entire operation, the roller entering the cam slot at the desired location.

#### Inside Profile and Base Recess

A number of Yeates, and Lyall special

ing with further machining, the shells are weighed to determine the amount of metal to be removed from the base to bring them to the required weight, which at this point should be 88.8 pounds, with a high or low limit of 8 ounces. The stock removal is about 1-64 of an inch for each two ounces. After the shells are faced to weight,

FIG. 9.  
DIAGRAMMATIC REPRESENTATION OF SHELL  
WAVING DEVICE.

is shown in Fig. 6. The cam plate is secured between the headstock and the tailstock, and provision is made for slight adjustment in the containing brackets C and D. The cam rolled is secured to the cross slide of the

lathes are at work forming the inside nose profile, the latter being equipped with pneumatic chucks for holding the

they are taken to a number of Bullard lathes to have the base recessed out. With very few exceptions, the base

plates are now inserted in and riveted without recourse to the threading process. The recess for the base plate has a diameter of 4.5 inches and a depth of 0.5 inch, the outer edge of the disc being slightly chamfered, to allow the metal around the edge of the recess to close over it when being riveted in.

#### Grooving and Waving

The grooving and waving is performed in manner similar to that on the smaller

given their final shop and Government inspection. The latter is very thorough, and every shell is subjected to careful examination. When faults are discovered, they are rectified wherever possible, so that rejected shells are kept as low in number as possible. The painting of the shells is accomplished by means of the device shown in Fig. 12. The small motor operates continually, the shell being placed in position and

FIG. 12. DETAIL OF SHELL PAINTING DEVICE.

shells. The groove is first roughed-out to the desired depth, leaving ridges of sufficient width to obtain the ribs and form the proper wave which in every case is irregular to prevent any possible slip of the copper band. After the ribs have been formed, the sides are undercut, with a special attachment secured to the tool post of the carriage. Several chisel cuts are afterwards made across the ribs to allow the free escape of the air, when the bands are being pressed on.

The grub screw hole, for the brass socket is next drilled and tapped, after which the shells are sand-blasted to thoroughly clean the interior of the bore so that the varnish will form an even coating on the interior walls.

#### Finishing Base Plates and Copper Bands

Following a preliminary inspection, the base plates are put in and riveted, after which the square tips are sawn off by several Racine saws. The base is then faced off, and the shells taken to the varnishing room to receive a coat of varnish on the inside surface. It is very important that this coating should cover the entire surface and be evenly distributed, as the action of the explosive (which is placed therein) has a very deteriorating effect upon any exposed metal.

The copper bands, which have previously been prepared, are now forced over the base of the shell, to a position over the groove. The shell is then placed in a hydraulic press and the band pressed into the groove under a pressure of about 1,500 pounds per square inch. Several Jenckes band turning lathes fitted with air chucks are operating on the finishing of the copper bands.

After the shells are marked, they are

revolved by pressing the framework forward, thus bringing the disc H in contact with the small driving wheel L, attached to the spindle of the motor. After the paint has thoroughly dried, the shells are again inspected. Crating in readiness for shipment follows.

#### HANDICAP OF BAD BELTING

HOW many machinery users possess even an elementary knowledge of belting? Comparatively few, says a writer in Page's Weekly, yet belting in many cases serves as the great muscle of the workshop for extended power, and if the leather is wrongly fitted, as it often is, and badly-made as some specimens undoubtedly are, the belting capacity cannot be equal to specifications. Many a workshop is losing power and cash daily through its belting.

#### Leather Belting Characteristics

Putting aside woven belting, which has characteristics of its own, let us see how leather operates. The tenacity of good new belt leather varies from 3,000 lb. to 5,000 lb. per square inch of sectional area, and thickness averages  $\frac{1}{4}$  in. Clearly, if the tenacity "varies," a danger point exists somewhere when two leathers of different tannages are joined in one belt, although that danger may be well beyond the usual stress limit. Those two leathers may have inherent differences, as well as the differences imparted by separate tannages and separate modes of finish, so that to specify one stress limit in pounds for two different leathers may prove misleading. The maker of the machinery concerns himself with power, speed and pulley dimensions, and the user is concerned very materially in the strength per inch of width, and if tensile strength in pounds per inch of width were added,

it is argued that the user would have a better safeguard.

Our view is that while a percentage of difference exists between one piece of leather and another, the user may rest satisfied that if he purchases from a reputable maker, in accordance with clear and practical specifications, he may count on obtaining a sound article at a fair price. "Cheap" belting should be classed with other "cheap" goods. Assuming that the right belt is purchased, the fitting should receive the greatest care. Any leather will stretch after a period of use, and if the stretching is excessive then troubles ensue. The removal of undue stretching is as important in its way as the original purchase, for erroneous removal has a sequel in hampered work. A thick belt stretches more on the outside than a thinner one because such a belt cannot lie so closely around the pulley. The greater thickness of material requires greater bending force, and greater friction is set up.

#### Belt Thickness

Uniform thickness throughout is desirable in all cases, and its influence is particularly emphasised with regard to light high-speed machinery. The cumulative importance of this is illustrated by comparing the velocity of belts on ordinary shop line shafts (1,000 to 1,500 ft. per minute) with the speed of lathe belts, which ranges from 1,500 to 3,000 ft. per minute. The item of centrifugal force has no material bearing upon the line shafts at ordinary velocities, but when the speed reaches 3,000 ft., or more, the centrifugal force tends to reduce the amount of power which a belt is capable of transmitting. Recently, we have heard of belt speeds above 5,000 ft. per minute, due to pressure of work, but such speeds should be discouraged.

Camel-hair belting constitutes a subject which should be dealt with in a separate article. Woven belting exhibits great strength and flexibility, regardless of temperature, water, steam, chemical fumes, etc., yet it is never likely to displace leather in the estimation of a host of engineers. Link belts are useless at high velocities, although they are superior to leather belts at low speeds. In a number of instances compound belts formed by placing one belt upon another have been found to add most substantially to the power transmitted.

Some really useful substitutes for leather belts are on the market, and cotton may have a greater future on the pulley than it enjoys at present. Considering that the fibre is tested to 1,500 lb. per square inch, a belt of such material is capable of great service in the workshops.

# PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data  
and Ideas Evolved from Actual Practical Application and Experience

## MACHINE SHOP ADAPTATION TO LABOR SHORTAGE

By D. A. Hampson

**D**URING the past two years, the supply of skilled men in the mechanical trades has been woefully short of the demand—the chances of “picking up” a few first-class machinists being about as slim as those of finding grand opera tenors. Three courses have been open to shop managers, i.e., to train new men, to instal automatic machinery and appliances, and to conserve the energies of their employees so as to secure the greatest possible production. To this end, a shop of 35 men doing a general machine business and small accurate manufacturing adopted some methods as follows:

A beginning was made with the receiving and shipping end. As the plant was away from the railroad, all raw and finished materials had to be trucked. Raw material came in as tubes and pipes, rolled stock boxed and unboxed, barrels of castings and forgings weighing up to 500 lbs. The finished product went out in heavy boxes and barrels, also in crates, weighing up to 2,000 lbs. All the foregoing came and went through a ground level door at one end of the building. The factory building stood in a large space of fairly level ground and was 150 feet square. Owing to the diversity of products, different classes of work were done in different parts of the building, the tools being arranged to suit. The castings, forgings, and bar stock went largely to separate departments. This much description is necessary to give a clear idea of conditions—which it will be noted are not unlike those found in many shops. Truck men delivered goods to the shop floor and loaded from there. To transfer the heavy barrels and (generally) 20 ft. bar stock, shop help was employed.

### Improving Shipping Facilities

While this item of transferring had at one time been considered, it was not a dead loss, for it was added to selling price—the customer willingly paying, because the products were mostly patented and were labor-saving supplies of merit. When there came a shortage of men, however, the matter became too big to overlook. The discomfort of having large doors open in winter, the time Jim's miller was idle while he was giving a hand with the barrels, the time of three men who had to stand aside while

the long boxes were shunted around past the inspection bench, and that of the two or three laborers who were always required anyway, had finally to be considered. As the time loss figured up as high as 30 hours per week, there was little hesitation about putting some betterment into practice.

A drive was graded part way around the building so that a wagon body was on the floor level at certain points and above it at others. A loading platform with storm doors was built, and receiving doors and hatches were cut for the different departments: the object was to put the entire transferring on the truckman. The barrels were rolled down a slight incline to the very spot where the forgings were first used, long pipes and boxes slid out of the wagon through the hatches on permanent rollers to a position directly in front of the storage racks, machines were rolled out directly into the wagons—there was no lifting for the truckmen, and his work was easier, besides there was nothing for the shop men to do.

### Elimination and Simplification

Inside the shop, many of the merely physical operations that machinists were doing were given to boys or laborers, or eliminated altogether. Several more drinking fountains were installed and toilets put in — this saved the time it took to walk often 250 feet several times a day. It had been customary for the men using machine oil, cutting oil, or compounds to fill their own squirt cans and the pots on the machines. This work was given to a boy whose duty it was to make four daily rounds and replenish the supply. The same boy gathered up tools that were out of place and returned them, carried lathe and planer tools to the blacksmith, and other similar work. Once a week, the boy doled out the supply of waste.

Because of the interruption and loss of time therefrom, sweeping in the daytime was abandoned, and was done at night along with cleaning out of the chip pans. The night man was instructed in the repairing of belts and did all of this work except breakdowns, which were rare after the machine hands got the habit of watching out for and reporting loosened laps and frayed laces.

Racks were built near the drills, the arbor press, and, on walls, and tools like taps and dies, reamers, arbors, drills, wrenches, etc., in common use were taken out of the tool room and put in

the racks most convenient to the place where used. While this did not improve the general appearance of the room, it saved a great deal of time spent in running to the tool room, waiting, checking, etc. The loss from this method (which might seem like retrograding) was no more than under the old system and the gain was great.

Quite a saving of machinists' time was effected by training a couple of bright helpers in the rudiments of setting up work. If, for instance, a pulley was to be bored, a helper changed the faceplate for a chuck, got out bolts and clamps, and roughly trued up the piece, turning the job over to the machinist who did the accurate centering and boring. The helper put the tools away when the job was done. By so going around ahead, the helpers gave the machinist a chance to do a maximum of skilled work. Some work like rough planing, roughing cuts on heavier castings, and practically all of the drilling was turned over to helpers altogether. These arrangements were mutually agreeable—the machinists being glad to be relieved of the hard physical labor, and having in consequence more energy for the closer work. The helpers were glad to learn and to be put in the way of advancement. In connection with general machine work, an important point was observed and saved a good bit of time. All castings on receipt from the foundry were marked on the finished surfaces and then the helpers went over them looking for lumps, scabs, sand on the faces, and particularly in corners wherever cutting had to be done. These places were well cleaned and prevented many a broken off and spoiled tool.

### Wholesale Labor Saving

On the sensitive drills it had been the practice to use squirt cans with cutting compound, and to clean jigs with brushes. A pipe service was put in that did away with the cans and brushes by supplying a flood of liquid, and most of the jigs were fastened down. In some cases more than half of a man's time was saved. Drills in sufficient quantity were supplied and kept sharp by a boy so there was little delay there.

Realizing that the secret of rapid assembling is in accurate machine work, better and more gauges were made, parts were completely jigged, and more inspections were made. Savings of from ten to two hundred per cent. were thus made. Simple devices for doing away with the use of hammers, hand punches,

pliers, etc.—tools which have to be picked up and laid down, were perfected.

In the milling machine operations, pronounced savings were effected. This work was all on Lincoln and semi-automatic millers and the cuts were short necessitating a man for each machine or each two of the latter. The feed screws in some machines were lengthened out to suit the new fixtures made. These fixtures, as far as possible, held long rows of parts and while they were cutting, the operator could load up two others.

One battery of six machines that had been run by three men was so arranged that two men were no longer needed, and were given other work. Compressed air fixtures were applied for clamping the work and the air valve was operated by a dog on the table, so that the operator had only to "click" the feed on and later return to find the work milled, the table returned, and the work loosened up. To facilitate his getting about and forestall fatigue, his seat was set on rollers running on a track before the row of machines and then after loading up his six machines, he could give a shove and bring himself back to the starting point with a rush.

The shortage of men thus started what proved to be an efficiency campaign. No part of the plant escaped. In the drafting room, fewer tracings and blueprints were made of parts that would not be wanted again. Boys and helpers moved the tote boxes around where skilled men had done it before. Packing boxes were standardized and made in quantities. Whenever possible, the final inspector placed his parts directly in the shipping cartons or boxes. These changes secured a greatly increased production and the loss of some employees was not so keenly felt as it would otherwise have been.

### TRY-SQUARE HOLDER

By C. H.

IT is a difficult matter to keep a tool such as a square on a machine without knocking it over, or having it fall on the floor. Especially is this true when

BLOCK FOR HOLDING TRY SQUARE.

using one to square up work being ground on a disk-grinder, where the vibration of the machine jars it off the

table. A square is an expensive tool and requires care in order that it will not become nicked, or out of true. A useful suggestion is shown herewith of a try-square holder. It is simply a block of wood having a groove cut across the face wide enough for the heel of the square to fit into. The block will always keep the square upright on a machine or wherever it is used.

### HACK-SAW MACHINE STOCK SUPPORT.

By J. E. C.

WHEN cutting off pieces from long bar stock in a hack saw machine, it is necessary to support one end of the stock in order to hold it straight and keep it from tipping up in the vise; also, so it can be easily moved along after a piece is cut off. In the accom-

SUPPORT FOR STOCK IN HACK SAW

panying sketch is shown a cheaply contrived stock-stand that can be produced from 1 in. angle-iron. Two pieces indicated at A, are cut out where the bend is made in the legs and cross-stays are riveted on the lower part of the legs to keep them from 2 in. thick by 6 in. square. In the center of the block, fastened with a bolt and washers, is a cast-iron bridge containing a steel roller on which the stock is supported. A rod extends through the roller as shown. The height of the stand should be directly on a line with the seat of the vise. The apparatus is light and rigid, and is easily moved about.

### A NOVEL DEPTH-GAUGE

By Alden Street

THE depth-gauge shown in the accompanying art for measuring depths of holes, tee-slots, etc., is designed on a simpler principle than the most of those in general use. The block A consists of a piece of square cold rolled stock, having a depth-finder or rod B. Instead of the usual screw for holding the rod in place, a small pin C is driven in the block A, passing slightly through the rod hole as shown. The rod B is filed

or slightly flattened off along the side as at D, so that it will have a free-fit in the hole. To locate a depth, the rod B is simply pushed down, and then given a slight turn which binds it firmly

SIMPLE FORM OF DEPTH GAUGE.

against the pin C. A hole is drilled through the center of the block for holding the depth-finder so that it may be laid flat in the tool-chest.

### WEIGHT CHART FOR CYLINDRICAL STEEL STRUCTURES

By Woodworker

IN the August 17 issue of Canadian Machinery a chart appeared under the title, "Chart for Finding Weight of Cast Iron Pipe." Here is a similar chart, except that it applies to cylindrical steel structures. Its range, as will be noted, is very wide. The length (or height) of the structure may be 100 ft., diameter 100 ft., and thickness of steel may be anything from 0.1 inch to one inch.

For example, how many tons of steel would be needed to build the cylindrical shell of a water tank 20 ft. long, by 10 ft. diameter, steel being 0.5 inch thick? Connect the 20 (column A), and the 10 (column E), and locate the intersection with column B. From the intersection, drop over to the 0.5 (column D), the

CHART FOR FINDING WEIGHTS.

intersection there with column C gives the answer—about 5.7 tons. The basis of the chart is 2240 pounds per ton.

# Engineering Exhibits at The Canadian National Exhibition

## Staff Article

*Some of the products on view in the Machinery Hall still bear evidence of war-time influence, but at the same time the trend of future events is witnessed by a general advance in quality, design and application indicative of a national determination to still further enhance the reputation already earned by so many of our Canadian manufacturers.*

**E**ACH succeeding year since the outbreak of the war has witnessed the increasing importance of the engineering industry as one of the deciding factors. The co-operation of the Imperial Munitions Board with the authorities of the Canadian National Exhibition has resulted in a unique display of war products by the leading munitions firms of the country.

Housed in what was formerly the education building, these exhibits possess a double attraction for the discriminating observer: not alone because of the destruction which marks the termination of their existence as manufactured products, but also because of their significance as evidence of the ability and versatility of our manufacturing firms. From motor cars to fuses, from bridges to cartridge cases, from bricks to steel shells, no transfer of effort has been too great to prevent complete success, and as if such incidents were not convincing enough, there is the case of the steel companies who had to produce a new type of steel and at least one concern which is producing copper bands from the raw metal.

### Steel Making

Prominent amongst the large exhibits is that of the Nova Scotia Steel & Coal Co., which consists of samples of the various substances which enter into the composition of shell steel. Coal, coke, iron ore, lime stone, magnesite, etc., are all shown in the natural state just as the steel maker uses them. The gradual

transformation of these materials into a real live 9.2 in. shell is illustrated by specimens of pig iron, a full size ingot of shell steel weighing 6670 lbs., stand-

the Dominion Arsenal, Quebec, and the Russell Motor Car Co., Toronto show products of the machine shop which vie with each other for accuracy and com-

DISPLAY BY DOMINION ARSENAL, SHOWING SMALL ARMS AMMUNITION, SHRAPNEL AND BANDS.

ing eight feet high, and various sizes of bars into which the ingot is rolled and from which the different shells from 18 pdr. to 9.2 in. are forged. The exhibit is in the charge of M. P. Graham who displays pardonable pride in its completeness.

### Fuse and Cartridge Making

As if in contrast to the massiveness and weight which characterizes the exhibit referred to above, the displays of

plexity of manufacture, smallness of component parts, and rigidity of specifications to be met. The former display illustrates the making of small arms ammunition i.e. cartridges cases, bullets, clips, etc., with samples of the punches, dies, traps, gauges and other small tools used in their production, the raw material being shown in successive stages as each operation is completed. Brass cases and copper driving bands for 18 pdr. shells are also exhibited from the copper

NOVA SCOTIA STEEL & COAL CO.'S EXHIBIT OF RAW MATERIALS, STEEL FORGINGS AND FINISHED SHELLS.

ingot and brass disc through the successive operations.

The various stages of fuse manufacture are shown in a similarly complete

Whitehead torpedo and the army by a captured German field gun. The torpedo is ably explained by Lieutenant Miller of H.M.C. Torpedo Depot, the exhibit

Other exhibitors include:—Brown's Copper and Brass Rolling Mills; John Bertram & Sons Co.; Brandram-Henderson Ltd.; Canadian Car and Foundry Co.; Canadian Explosives Ltd.; Deloro Mining and Reduction Co.; Empire Mfg. Co.; Ross Rifle Co.; Standard Brick Co.; Standard Chemical Co.; H. Bock; Universal Tool Steel Co.

### Machinery Hall

The gathering of machinery builders, dealers, and buyers which takes place in this department retains its hold on the trade as an annual event of importance, having shown a tendency of recent years to becoming somewhat of a counterpart of those conventions of kindred societies which in other countries have become important factors in various industries. The opportunity for renewing old and making new acquaintances is accepted by many while the value of the event as an occasion on which to introduce new designs and models is too well known to require any comment. Armstrong, Whitworth of Canada, have provided a tasteful reception room where the visitor may investigate in ease and comfort the merits of the first high-speed tool steel to be made in Canada. Prominent among machine builders is the Canada Machinery Corporation who have arranged their display in an exceedingly creditable manner. A model of a field gun constructed of ball bearings is a feature of the Chapman Double Ball Bearing Co.'s display, while an emergency outfit of oxy-acetylene cutting apparatus which has already saved many lives in railroad wrecks is a fea-

EXHIBIT OF IRON AND WOOD-WORKING MACHINE TOOLS BY THE CANADA MACHINERY CORPORATION.

manner by the Russell Co. Parts in profusion enter into the construction of these important articles, the extreme accuracy combined with oddness of shape or smallness of size rendering their successful manufacture an accomplishment of no mean order.

### British and Russian Shells

The Dominion Bridge Co., along with Montreal Ammunition Co., and Dominion Copper Products Co., shows sectional specimens of each operation on 18 pdr., shrapnel and high explosive, 4.5 in. 60 pdr. and 6 in. British, and 75 mm. Russian forgings; while copper bands for all sizes and brass cases for the smaller sizes are likewise fully exhibited. The companies are represented by J. H. Bradley, and their record is displayed on a special poster which shows that over 6,000,000 brass cases alone have been shipped to date with proportionate outputs of other items.

A novel treatment of their stand is shown by the Canadian General Electric Co., and Canadian Allis-Chalmers who display a number of photographic transparencies showing numerous scenes in their various factories where munitions are now being produced. These companies are making a greater variety of munitions than any other firm in Canada, amongst their product being 3 in., 6 in., 7.5 in. and 9.2 in shrapnel for the navy and 18 pdr., both types. 4.5 in. and 60 pdr. for the army, including cartridge cases and percussion primers, numerous samples being displayed in an attractive manner under the direction of J. F. MacLean.

Both branches of the armed forces are represented, the navy by an 18 in.

being loaned by the Dept. of Naval Service, Halifax. Compressed air is supplied to the apparatus so that the propellers, rudders and all controlling gear may be seen in motion. The field gun was captured by the 9th Lanciers in Aug, 1914, when the enemy was within 25 miles of Paris.

The moving picture exhibit is staged in the annex and gives a lucid insight into the actual conditions under which our munition workers are now doing their bit throughout the country.

DOMINION BRIDGE CO.'S EXHIBIT OF SHELL CASES AND FORGINGS FOR BRITISH AND RUSSIAN SHELLS.

ture of the Carter Welding Co., exhibit. The Canadian Hoskins Co., are showing a full line of both gas and electric furnaces while the belting industry is represented by Dominion Belting Co., and D. K. McLaren. The A. R. Williams Machinery Co., exhibit an extensive line of machinery including special toy machinery in the process building, and amongst new comers is noted the Thwing Instrument Co., showing pyrometers. Following is a list of exhibitors and representatives.

**Armstrong, Whitworth of Canada, Montreal**—High-speed steel and small tools. Representatives, H. Johnson, J. L. Hynes, Rooms 820-1 King Edward Hotel.

**Armstrong Cork and Insulation Co., Toronto**—Insulating materials, cork products, models of power plant equipment showing applications, etc.; samples of diatomaceous earth. Representatives, J. C. Kyle, G. C. Albertson, H. Johnson.

**Aylmer Pump & Scale Co., Aylmer, Ont.**—Hand and power pumps, scale trucks, water supply systems.

erating machinery and supplies. Representatives, F. F. Allison, C. Bower, C. E. Allison.

**Carter Welding Co., Toronto**—Davis-Bournville oxy-acetylene apparatus, mechanical equipment for cutting, emergency outfits for rescue work; demonstrations in progress. Representatives, P. Sorley, H. W. Carter, C. Steadman.

**Cowan & Co., Galt, Ont.**—Selected types of modern wood-working machinery. Representatives, W. Cowan, S. F. Barrows, W. C. Clark.

**Geo. W. Cole Co., Toronto**—Steam specialties, including Cole boiler feeders, heaters, etc. Representative, Geo. W. Cole.

**Climax Baler Co., Hamilton**—Machine for packing waste paper. Representatives, H. Robinson, Melville Moore.

**Canadian Hoskins Co., Walkerville, Ont.**—Gas and electric furnaces, pyrometers, etc. Representative, G. F. Shepherd.

**Dodge Mfg. Co., Toronto**—Dodge wood pulleys, shafting, bearings, hangers, demonstrating line of transmission equipment. Representatives, T. F. Gary, J. F. Haas.

**Dominion Belting Co., Hamilton**—Stitched belting of all sizes for power transmission and conveyor equipment. Representative, J. Scott.

**Day Name Plate Co., Toronto**—Representative, L. S. Day.

**Elliot Wood Worker, Toronto**—Combination

**Pratt & Whitney Co., Dundas, Ont.**—Samples of fine tools, cutters, gauges, etc. Representatives, M. B. Davidson, H. Webb.

**Small Brothers, Smiths Falls, Ont.**—Evaporators and supplies for the maple sugar industry. Representative, Len Edmonds.

**Tallman Brass and Metal Co., Hamilton**—Brass and aluminum ware and castings, anti-friction metal, etc. Representatives, Geo. McKnight, R. H. Eckert.

**Toledo Scale Co., Toronto**—Scales.

**Thwing Instrument Co.**—Thermo-electric radiation and electric resistance pyrometers, indicators and recorders. Representative, J. DeVon.

**Williams Machinery Co., A. R., Toronto**—Stationary and marine gasoline engines—A. Kischel and R. Hunter. Machine tools and wood-working machines—T. B. Reid, F. Barber, T. J. Eason and A. Hasen. Toy-making machinery in Process Building—C. Foderingham and W. T. Peck.

## SHELL BOX PRICES—ARE THEY ADEQUATE?

ALTHOUGH we have heard a great deal of discussion recently in regard to the shell box business in Canada, bearing chiefly upon the prices at which contracts have been awarded by the Imperial Munitions Board, we, says The Canada Lumberman and Woodworker, have avoided discussing the subject to any extent, feeling that it was wise to wait until the situation had been developed more fully and the pros and cons of criticism that we have heard had been more definitely sifted out. We have heard so much criticism during the past few weeks, however, that it seems to us that the situation now calls for some publicity. Briefly, the main point of criticism that we have heard from many quarters is to the effect that contracts have been let at such low prices that there is no profit in them for the manufacturers. It may be thought by some that this is an indication of good business on the part of the Government, or rather on the part of the Imperial Munitions Board, but when the matter is analyzed it is not difficult to see that by following out such a course the Munitions Board is really cutting off its nose to spite its face.

We cannot put this matter any more clearly or forcibly than in the words of a manufacturer and wholesaler who discussed the matter with us recently. This man, representing one of the most important Canadian firms, finds that in selling material to the box manufacturers he is up against a very different proposition to any that he has had to face in the past. In spite of the fact that he is dealing with firms that are handling very large orders for the production of shell boxes, he has to be on the watch every minute of the day in connection with the credit end of the business. He is gradually eliminating many of the customers whom he took on at first, finding that it is not safe to give them credit, and that without credit they cannot handle the business.

### Production Cost

"In the first place," this lumberman says, in speaking of the Bethlehem box,

TIME AND GRAZE-FUSE PARTS, COMPLETED FUSES, ETC., ILLUSTRATING WORK BY RUSSELL MOTOR CAR CO.

**L'Air Liquid Society, Toronto**—Oxy-acetylene welding apparatus, gas generators; work in progress. Representatives, L. B. Deane, A. M. McDougall.

**Boiler Repair & Grate Bar Co., Toronto**—"Gate" firebrick lining for boiler furnaces, 20th Century grate bars. Representatives, C. W. Andrews, A. H. Hetta. Also products of United States Graphite Co., Saginaw, Mich., represented by E. D. Robinson.

**Baines & Peckover, Toronto**—Exhibit of tool steel, crucible vanadium and cold rolled steel; expanded metal, chain, wire and kindred products. Representatives, C. R. Peckover, W. M. David, J. A. Steven, H. Marshall, H. Febet.

**Bolco, Ltd., and Shell Bar Grate Co., Toronto**—Boiler compounds and grates. Representative, Mr. Downes.

**Canada Machinery Corporation, Galt, Ont.**—14-in. tool room lathe, completely equipped; 24 in. by 10 ft. quick-change, double back-geared engine lathe; selected wood-working machines, including hollow chisel and chain mortisers, 12-spindle dove-tailer, etc. Representatives, D. King, P. D. Burton, W. J. Irving, M. Preston.

**Cleveland Pneumatic Tool Co., Toronto**—Full line of Cleveland apparatus, hammers, drills, grinders, riveters, couplings and accessories. Representatives, C. D. Garner, H. F. Olrich.

**Chapman Double Ball Bearing Co., Toronto**—Transfer trucks, transmission bearings and various ball-bearing appliances. Representatives, W. C. J. Hockin, M. J. Fulcher.

**Cling-Surface, Buffalo**—Exhibit of special preparation for maintaining efficiency of driving belts. Representatives, J. B. Faatz.

**Canadian Ice Machine Co., Toronto**—Refrig-

wood-working machines, floor sander, etc. Demonstration in progress. Representatives, W. A. Elliot, Frank Elliot.

**Foster, W. L., Toronto**—"Carbic" system of oxy-acetylene lighting. Representatives, A. E. Haigh, M. V. O'Neill.

**Goodyear Tire & Rubber Co., Toronto**—Goodyear products. Representatives, W. H. C. Crosby, R. F. Fox, — Wood, F. E. Holland.

**Garlock-Walker Machinery Co., Toronto**—Giddings & Lewis tool room lathe, Hepburn 8 in. shell lathe, wood-working machinery, including "American" double arbor saw table and Linderman dove-tailer; display of Thor pneumatic tools, and machines in operation. Representatives, W. Garlock, Jr., A. B. Walker.

**Holden Co., Montreal**—Pneumatic and electric portable tools, rock drills, railway supplies, etc. Representative, J. B. Wilson.

**Hutchinson Woodworker and Contracting Co., Toronto**—Wood-working machinery in operation. Representatives, M. Hutchinson, P. H. Bradley.

**Jones & Moore Electric Co., Toronto**—Electric motors and machinery in operation.

**McLaren, Ltd., D. K., Montreal**—Leather and balata belting, wood and pressed steel pulleys, transmission accessories. Representative, W. S. Hamilton.

**Massey-Harris Co., Toronto**—Gasoline engines in operation, portable saw outfits, farm appliances, etc. Representatives, N. A. McIntosh, E. Greig.

**Morrison Co., J. L., Toronto**—Bookbinders and paper machinery. Representatives, D. Brown, W. Duncan, C. Leake.

**Positive Clutch & Pulley Works, Aurora, Ont.**—Power transmission apparatus. Representatives, R. A. Fraser, — Beard, W. Day.

"there is the question of cost for the production of shell boxes. The cost of labor, the cost of bands, steel, etc., are all very much higher than they were for the old boxes, and the price of lumber should be higher, but we cannot get it. The man who makes a contract for the box, in the first place, cannot cut down his labor cost, and there is a close enough combination among the steel producers to prevent him from cutting down the cost of steel. The only way in which he can keep down the cost is by trafficking around with his order for lumber until he can get it at the lowest possible price. Naturally, the first result of this is a tendency on the part of the firm from whom he buys the lumber to furnish him with an inferior article. The lumberman has to do this in order to get his cost out of the order at all. It costs just as much more proportionately to produce lumber to-day as it does to produce steel.

#### Disposition of Contracts

"Then there is another feature of the situation that is of great importance. A large portion of the orders given out for shell boxes during the past two months have gone to concerns that are being run by a liquidator, or to concerns whose credit ratings are such that they are not entitled to the regular lumber terms of credit. The consequence is that if you want to sell material to them you either have to stand out for a straight cash discount before you unload the stock or take your chance of ever getting your money for your goods. Labor has no such a thing as a credit term. It must be paid for each week. Steel concerns will not give credit. As a consequence, the box manufacturers pay for their labor and pay the steel man, while the lumber manufacturer and dealer either holds his lumber or takes a considerable risk. If the box manufacturer can make good and work out a profit—which is questioned by most of the authorities upon the subject—then the lumberman will be paid; but if the box manufacturer falls down, as it is predicted that many of them will, the lumber dealer and the manufacturer of lumber are stung.

#### Lumberman's Protection

"The question, then, arises as to what protection the lumberman can get under these circumstances. Will the Government permit him to attach moneys due, or will they throw out an application for attachment, the same as they do when you try to attach the wages of a Government employee; or, provided they permit you to attach these moneys, will they then cancel the manufacturers' contracts for boxes? In the face of the great quantity of orders that have been placed for these boxes and of the fact that so many of the manufacturers are now falling down on their deliveries and

dropping out on their contracts, would it not be possible for the Imperial Munitions Board to do something in the way of assisting those who are supplying these materials, so that they may be secure as to their money? The supplies of material are just as necessary to the quick and efficient delivery of munitions and boxes as the work that has to be done in their production, and are just as worthy of consideration from the Munitions Board.

#### A Constructional Anomaly

"There is another feature in connection with the production of the Bethlehem box that calls for some criticism. In the production of these boxes it is stipulated that the diaphragms are to be produced from one quarter and five-sixteenth inches veneer. This material costs about three times what it would have cost to produce the diaphragms in solid wood, and it is very questionable whether they are any better in veneer. The only material effect that the use of veneers for this work has had, so far as we can see is that practically all of this material, instead of coming from Canadian manufacturers who are paying taxes and bearing the brunt of our financial troubles, is coming from veneer manufacturers in Wisconsin, who, of course, are paying a duty to our Government when the stuff is imported, but are having 99 per cent. of the duty refunded as soon as the boxes are shipped out of Canada. On the whole, is there anything fair or equitable in the manner in which the Imperial Munitions Board are treating the lumbermen of Canada in this shell box situation?"

If the price at which shell boxes are now being ordered by the Munitions Board is not sufficient to permit of the manufacturers doing their business in a sound and moderately profitable basis, the sooner the fact is properly appreciated by the board the better it will be for all concerned. Our definite conviction is that the board should make a detailed study of the cost of production of its shell boxes and make sure that orders given out are upon a price base that will not increase the financial difficulties of manufacturers in Canada to-day.

#### TRANSMISSION SAFETY—III.

NUMEROUS accidents occur to men whose duty it is to oil the bearings of overhead shafting. It is highly desirable to prohibit the oiling of shafting while it is in motion, but this is not always practicable, when the bearings are of the usual type. A special form of bearing, known as a "ring bearing", is favored by many shops, and it is to be commended to the attention of those who have not tried it, inasmuch as it greatly lessens the likelihood of accidents from oiling. This form automati-

cally supplies oil to the bearings from a small reservoir which holds a sufficient amount to last for more than a week. The reservoirs throughout the shop can then be filled on Sunday, while the machinery is idle, and in this way the danger from oiling moving shafting is entirely obviated.

When the bearings are of the ordinary type, they can be oiled with a fair degree of safety by doing the work from elevated platforms or walks, properly railed and running parallel with the shafting for its entire length. Provision can often be made for platforms of this kind when designing and laying out a shop, but it is usually a difficult matter to instal them in a shop that was erected without reference to them. Another method that can sometimes be used with advantage consists in erecting, parallel to the shafting, an overhead rail or track, along which an iron ladder travels by means of wheels or rollers. In most cases this plan is difficult of application in shops that are already in use, because the ladder would interfere with belts or pulleys, or with machinery on the floor.

Vertical pipes are sometimes extended through the floor over the shafting and immediately above the bearings, through which oil may be poured; but when this is done it is not easy to see how much oil reaches the bearing, and the attendant is therefore likely to use either too little oil, or else an excess of it. In the former case the bearing may run dry, while in the latter case a considerable quantity of the oil may be wasted. Special oil-cans are sometimes used, having necks or spouts bent in the form of a U at one end,—the necks being long enough to permit the oiler to lubricate the bearing while standing upon the floor.

#### EXHIBITION NOTES

Over 15,000 men did all or part of their training at the Exhibition Camp last winter.

Over 1,000 persons will take part in the performance daily in front of the grand stand at the Canadian National Exhibition this year.

Exclusive of live stock and outdoor exhibits there is an exhibit space at the Canadian National Exhibition of over 500,000 square feet.

The exhibit in the Fine Arts Gallery this year at the Canadian National Exhibition will comprise 200 masterpieces of French art representing all the schools of the present day.

Saturday, Aug. 26th, and Monday, Sept. 11th, are exhibitors' days at the Canadian National Exhibition, and the public are not admitted. On the other twelve days everything is in full swing.

# PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

## NEW DESIGN 14-INCH QUICK CHANGE ENGINE LATHE

A NEW design, 14-inch quick change engine lathe has been placed on the market by the Canada Machinery Corporation, Galt, Ont., its special purpose being to meet the requirement demand from small machine shops, technical schools, etc., for a tool embodying all up-to-date improvements, with at the same time the widest possible range of service. From the illustration and detail description that follow, it will be observed that the C. M. C. may justly claim to have achieved the ideal to which they aspired. In addition to having a contract to supply a number of these lathes for the machine shop department

We are advised that one of these lathes is included in the C. M. C. exhibit in the Machinery Hall at the Canadian National Exhibition now being held in Toronto.

As indicative of the handiness and adaptability of this lathe, reference may be here made to its thread-cutting provision, the latter admitting a range from 32 threads per inch to 5-inch lead, or one thread in 5 inches without changing a single gear. Again, by making extra change gears for the quadrant plate, practically any thread can be cut between the limits of 100 threads per inch and 5-inch lead. The relieving attachment supplied with the lathe, when equipped for toolroom work, is universal,

inverted vees of liberal proportions. The headstock and the tailstock each rest on one vee and one flat surface, while the saddle bears on two vees and also on the flat surface. The brackets attached to the bed are made with a tongue fitting into a groove in the bed, and the rack is of steel securely screwed and dowelled to the bed.

The headstock throughout is unusually massive, and is of the three-step cone, double-back geared type. It is made with split phosphor-bronze spindle bearings, which are provided with large oil wells to ensure ample lubrication at all times. The back gear eccentric has been moved to the front of the lathe instead of the back, a feature which has several

NEW DESIGN 14-IN. QUICK-CHANGE ENGINE LATHE.

of the new Technical School, Toronto, several are already installed and operating in the machine shops of Canadian metal-working plants, the managements of which, in every case, we are given to understand, express complete satisfaction both with the lathe workmanship and its quality and quantity product

being thus applicable to external, parallel, taper, angular and spiral reliefs, or to internal and end reliefs.

### Bed and Headstock Spindle

The bed is unusually deep and rigid, and is thoroughly braced with cross ribs of box section. It is provided with three

important advantages. In the first place, the eccentric handle is at the front of the lathe, avoiding the necessity of the operator reaching over the lathe with the accompanying danger of getting caught in the belt. Another advantage is that the wear on the front spindle bearing is much more even, this being

brought about because the back gear pinion, when the back gear is engaged, pushes the spindle down in its bearing in opposition to the upward thrust from the tool point. These forces, when the tool is at the pitch line radius of the spindle gear, balance each other, leaving only the pull of the belt to cause wear on the spindle bearing. With the back gear pinion at the back, the pinion and tool thrusts are both upward, causing greater wear on the top half of the spindle bearing. The gears on the head are entirely enclosed, but at the same time are readily accessible, as the head-stock is built up to the centre line of the spindle, and the gear covers drop on the planed faces at the front and back, being located by means of dowel pins. The covers lift off readily, simply resting in position by their own weight.

#### Spindle and Belt Shifter

The spindle is made from special high carbon spindle steel, and has a hole bored from the solid throughout its entire length. It is accurately designed to facilitate putting on chucks or face plates. The plain part of the spindle nose is longer than the thread portion, thus centering the face plates before they enter upon the thread.

A C. M. C. improved belt shifter, for rapidly and safely shifting the belts to any of the steps of the cone, is part of the regularly furnished standard equipment. It consists of an arm with a belt guide carried on the head, and provided with a self-locking pin for securing the arm centrally over each step. A corresponding shifter is provided on the countershaft, and by means of the manipulation of these levers, the belt may be shifted to any desired cone step in the minimum time without the operator endangering himself.

#### Feed and Screw-cutting Changes

The feeds and screw-cutting changes are instantly obtainable by the movement of a lever to any of the different locations shown on the index plate. The thread of the lead screw is used for screw-cutting only. The lead screw is reversed for right and left-hand threads by means of the reverse plate on the head. The forty-four quick change feeds are obtained in a new design of quick change box having only two handles. This arrangement is specially convenient, besides having the advantage of rapidity of action. A quadrant plate is supplied to carry the intermediate gear between the head and the quick change box. This makes the lathe elastic in its screw-cutting capacity, for by getting special gears made, practically any thread can be cut between the limits of 1/100-inch pitch and 5-inch pitch. All the quick change gears are made of steel.

#### Quick Thread Cutting

A quick thread-cutting arrangement is incorporated in the design of the head as

part of the regular equipment. This is accomplished by putting the reverse plate and gears inside the back bearing of the spindle in the head, means being provided for sliding the reverse plate 13/16 of an inch, so that the stud gears mesh with the cone back gear pinion, which is of the same number of teeth and pitch as the feed gear pinion on the spindle. The back gear is made of ten-to-one ratio, which means that when the back gear is engaged, quick threads may be obtained ten times as coarse as the threads on the thread index plate, with equal gears driving from the head to the quick-change box. Many useful pitches can be obtained with this device, such as 5/8 in., 2-3 in., 5-6 in., 1 in., 1 1/4 in., 1-2-3 in., 2 in., 2 1/2 in., 3 1-3 in., 4 in., and 5 in. The screw-cutting capacity of the lathe is vastly increased by this device.

#### Apron, Feed Friction and Tailstock

The apron is of the double wall type, and all shafts and studs have double bearings. The rear wall of the apron is made heavy and solid with the top where it is bolted to the saddle. The front plate is readily removable, and is comparatively light. The gears in the apron are all steel, and, where running loose on studs, are bronze bushed. An improved feature is the position of the friction engaging knob. This knob is lower than usual on the apron, giving more room for the hand when grasping it, and what is most essential in obtaining ample clearance for the knuckles, one knob engages either the longitudinal or the cross feed by turning to the right or to the left. Another advantage claimed for this location for a feed friction clutch is the fact that they run faster in proportion to a given feed than in the lathe with two separate frictions. This means there is no difficulty in making the frictions hold, only a light pressure on the knob being necessary. The feed handle and the nut clamp handle are interlocked, so that the feeds and screw cannot be engaged simultaneously. The feeds may be reversed at the apron by the lower lever. The saddle is made with a trough all round the edge, and has wipers to wipe the bed clear of chips. A locking handle is located at the front of the saddle for use when cross-feeding. The cross screw and the top slide screw have micrometer collar adjustments. The compound rest swivel is graduated in degrees.

The tailstock is of substantial proportions, and is arranged to set over to turn tapers. The barrel is graduated in inches. The locking handle is always in position at the rear, and no separate wrench is required.

#### Universal Relieving Attachment

A universal relieving attachment can be applied to any of these lathes, and is only supplied as an extra. It is ar-

ranged to do parallel relieving, both internal and external, taper relieving, and angular and spiral relieving. Any angle of taper can be relieved as the motion is carried up through the centre of the swivel in the rest. The attachment is driven off the spindle gear on to a pinion shaft at the rear of the lathe. This pinion shaft gears on to a lower spiral gear shaft by means of change gears and a quadrant, which is carried on the rear wing of the saddle. The spiral gear shaft drives a cross shaft on the cross slide of the lathe. This cross shaft carries right and left-hand relieving cams. The relieving cams give a vertical motion to the shaft running through the centre of the swivel slide. This shaft is arranged to work on to either of two oscillating levers in the tool slide, one of which is used for internal relieving, and one for external relieving. Provision is made for adjusting the amount of relief from nothing to 1/8 of an inch, either internal or external. When cutting spiral reliefs it is necessary to reverse the lathe in order to run back to start the tool for the next cut. The timing of the oscillation of the tool slide is not interrupted by reversing the lathe, as the oscillating motion is going on all the time that the lathe is reversed. The depth of cut is adjusted by means of the cross-feed screw, the arrangement being such that full use of the cross feed screw is obtained at all times. If desired, the relieving attachment and the taper attachment can be used at the same time to relieve long slow taper reamers.

#### Taper Attachment

The taper attachment is supplied only as an extra. It is of improved design, and has a fine adjustment for setting the taper swivel bar by means of a worm with micrometer adjustment and segment. The connecting bar to the cross slide is guided at both front and back of the taper swivel bar, this construction overcoming the excessive cross-wind with the corresponding friction in the cross slide.

The lathe is furnished with a two-speed countershaft, friction pulleys, steady head, follow rest, two face plates and all the necessary wrenches. Other attachments, which are extras, embrace the following:—Universal relieving attachment, taper attachment, pump and pan, turret on saddle, turret tool post, turret on bed, automatic stop for saddle, all-gear head, and motor drive.

#### IMPROVED DESIGN INDUCTION FEEDER VOLTAGE REGULATOR

AFTER a considerable amount of engineering and experimental work, with a view to improving the electrical performance and mechanical details, the Westinghouse Electric & Mfg. Co., East

Pittsburgh, Pa., has placed on the market the improved design feeder voltage regulator, illustrated. This is a single phase induction regulator, known as type

REGULATOR UNIT REMOVED FROM TANK.

C. for 2,300 volts, 60 cycles, 10 per cent. regulation, and it is standardized in all ratings from  $5\frac{3}{4}$  k.v.a. to 69 k.v.a. The refinements secured in this new design have increased the reliability of the regulator in service, and have simplified and decreased the expense of the wiring necessary for installing accessories for automatic operation, in addition to improving the electrical efficiency.

The rotor is wound with form-wound coils, and constitutes the primary element. The short circuiting coils in the rotor are formed from a large number of turns of relatively small size enamelled copper wire, thus reducing the watts loss in these windings without decreasing the neutralizing effect for which they are provided. The stator core is of the frameless construction so largely used in induction motors. With this form of construction the cross section of the stator core is increased without a corresponding increase in size of other parts and of floor space, resulting in a decrease of iron loss and exciting current. Further, the insulating oil in which the regulator is immersed in the tank comes in direct contact with all surfaces of the stator core with more efficient cooling effect.

In a regulator the insulation of windings is of vital importance because of the severe conditions of operation. The

coils for both primary and secondary are, therefore, carefully insulated and impregnated, and are assembled in open slots. They are held by fibre wedges driven in small grooves at the top edges of the slots. Heavily insulated steel bracing rings are assembled around the exposed ends of the stator coils at both ends of the core. These rings are bound to the coils with cord, and greatly stiffen the coils against distortion from mechanical shock caused by current surges in the feeder during periods of line disturbance or short circuit. This feature is an important one, increasing the protection to the coil insulation and the factor of safety of the regulator in service.

An electrically controlled switch or auxiliary relay for the operating motor, formerly mounted separately from the regulator, is now mounted directly on the regulator top cover and includes the limit switch. This arrangement cuts down the number of wires required in the control circuit for automatic operation, and simplifies and lessens the expense of installation. The chance of failure in the control circuit is correspondingly lessened as well, and inspection of the wiring is made easy. The operating motor is provided with a quick acting magnetic brake as heretofore, but the operating mechanism has been changed, so that the regulator now re-

quires only ten seconds for the complete range of travel from maximum buck to maximum boost, 20 per cent. regulation.

The regulator is made as a unit, and may be quickly removed from the tank by simply unbolting the top cover, thus making inspection and repairs comparatively simple. The tank is formed from sheet steel walls with oxy-acetylene welded seams, and with top and bottom flanges cast on to the walls. This type of tank is the same as that used with Westinghouse oil insulated self-cooled transformers. It is strong without undue weight, and free from oil leakage. The radiation quality is necessarily very high.

## CANADA'S HUGE TRADE INCREASE

THE aggregate trade of Canada in four months has increased by more than 100 per cent. The July trade as shown in the monthly summary issued on August 24, the Hon. J. D. Reid, Minister of Customs, showed the phenomenal rise of 141 per cent., or \$139,860,450. The total trade for the month amounted to \$238,860,488, and for the four months ending July 31 it reached the total of \$766,372,832, as against \$371,646,906 in the corresponding period of last year.

Imports for consumption amounted in value to \$63,622,587 in July as compared with \$36,622,190 in July last year, while in the four months period they rose from \$134,729,377 to \$249,867,767. The July exports reached a value of \$104,964,270 compared with \$45,590,038. In the four months the exports have risen from \$159,168,259 to \$350,345,305. These are in the figures for domestic imports and exports only.

In the export of foreign merchandise there has been a notable increase, nearly one thousand per cent. The volume of these exports rose from \$11,494,457 in the four months of last year to \$122,627,072 in the same period this year.

An interesting feature of the statement is the substantial rise in the imports of free goods: there has been, however, a corresponding increase in the imports of dutiable merchandise, and the duty collected in the four months has risen from \$28,085,471 to \$46,063,507.

Shipments of Canadian manufactured products trebled in July amounting to \$38,264,136, while the exports of farm products amounted to \$38,585,309, or five times the total of July last year. Exports of foreign mine products, which were less than a million in July last year, reached a total of over fifty-four millions last month.

The Government building at the Canadian National Exhibition has 48,000 square feet of exhibit space.

COMPLETE APPARATUS WITH REGULATOR UNIT IN POSITION.

### AFTER WAR TRADE AND MERCHANT MARINE SUPREMACY

ONE phase of the after-war world trade and commerce possibilities that is being given much less attention than it deserves is that relating to the comparative strengths, or more properly speaking, dead-weight carrying capacities, of the then British and German merchant fleets. Due to the fact that the bulk of Germany's mercantile marine has been harbor-locked in her own and in neutral ports since the war started, tonnage losses through sinking and capture by Allied ships of war may be said to be almost negligible. It is computed, on the other hand, that Great Britain's merchant fleet alone will at the end of the present year be in round figures something like 4,000,000 tons less than its total on the outbreak of hostilities.

A twofold cause has been and still is in operation towards such a development, i.e., the maintenance of her international trade and the precedence given war vessel over merchant vessel construction. In the case of the former it was naturally to be expected in view of the risks encountered that a large percentage of merchantmen of various types and tonnages must succumb in the struggle with even less ruthless enemy submarine warfare than what has actually been experienced. As regards the displacement of merchant shipbuilding by that of ships of war, while it may be possible that less drastic measures would have sufficed, our sea supremacy being so intensely vital, erring on the safe side has had everything to commend it.

Reference has been made in these columns on former occasions to the practically certain trade war which will ensue immediately that on the battlefields of Europe is halted. We, as already indicated, will enter the struggle with a handicap equivalent to 4,000,000 tons less shipping available, and, for that matter unprocureable for possibly a decade thereafter to come. Germany's merchant fleet as we have already observed will be practically intact, and ready to start operations, and having been in pre-war days our most formidable rival both as regards shipbuilding and shipowning, she, unless steps be taken otherwise, cannot fail to assume pride of place in international trade. Irrespective of the preservation of her pre-war merchant fleet with the exception of some 300,000 tons, she is reputed to have added, and to be still adding, materially to what, with

the deduction of the above amount, may still be reckoned as an already respectable total of 5,250,000 tons.

It is computed that to make good Britain's 4,000,000 tonnage loss, ten years will elapse following the declaration of peace, and even then her normal annual output would have to be increased from 1,370,000 tons to 1,770,000 tons. The outlook, it must be admitted, is anything but reassuring, and when it is remembered that we will have to depend largely on our export trade to meet the cost of the war, and that arrangements have been made to blacklist entirely everything that savors of German origin, it becomes absolutely essential that we have on the sea a merchant marine as effective as that of its naval confrere, and as capable of victorious achievement as our armies now in the field.

To wait ten years to bring our shipping back to normal, is on the face of it ridiculous, for not only would Germany have been able to take advantage of the psychological moment, but she would, in the nature of things, at least be able to compete with us in producing new shipbuilding tonnage. As a remedy, and of course it must be a drastic one, it has been suggested that peace terms embody "a ship for ship" clause; incidentally, a money indemnity is thereby flouted. From every viewpoint, there will be few who will be found antagonistic to the proposal. We are familiar with the Old Testament dispensation which demands "an eye for an eye," a "tooth for a tooth," and "a life for a life," and making all due allowance for our living in a Christian era, the claim of "a ship for a ship" may easily both be pressed and satisfied.

Submarine piracy has deprived us of some of our largest and greatest masterpieces of naval architecture and marine engineering, as well as of a host of merchant vessels of varied type and size, and only by our demanding "ship for ship," in its type, tonnage and appointments, or their equivalent, will Germany be made to realize that she has been a party to submarine piracy.

Much of Britain's mercantile marine has been and still is employed in war-created service, which is equivalent to saying that such vessels have been subject to more or less reconstruction, and, on account of their exacting duties, will as a matter of fact be in line for more or less extensive overhauling when hostilities cease. Germany's bottled-up craft are, it is quite certain, being maintained at "concert" pitch. This is borne out by the statement—if true, of Herr Ballin, the German steamship magnate, which places the orders on the books of Fatherland shipyards at 1,250,000 tons. Such a total of itself comes within 120,000 tons of Britain's normal annual shipbuilding output. Its significance is more pronounced, however, when it is remembered that Britain's mercantile marine was in pre-war days four times as large as that of Germany. The idea is to have at least that ratio when the trade war begins, and no more effective way of reaching the objective is to be found than by Britain's peace terms making it essential that "ship for ship" be a front rank clause.

### HIGHLY SIGNIFICANT!

THE fact that a debenture issue to the amount of one million sterling by Canadian Vickers, Ltd., has received the Imperial Treasury authorization, gives indication that not only is the importance of this enterprise highly appreciated in Home Government circles, but that considerable developments may be expected in the scope of its operations. Shipbuilding on a much more extensive scale than was perhaps originally planned will doubtless be the principal direction in which the additional capital will find an outlet.

## INDUSTRIAL NOTABILITIES

**W**ILLIAM JAMES CLUFF, president, Canada Pipe & Steel Co., 87 Church Street, Toronto; president, Cluff Bros., Ltd.; president Cluff Manufacturing Co.; president, Security Co.; director, Guardian Realty Co., was born at Toronto, March 20, 1877, son of James and Sarah (Percley) Cluff. He received his education in Toronto public schools, and entered on a business career as clerk with the Toronto Radiator Company in 1892.

He took charge of the Canada Iron Pipe Co. in 1906; reorganized and re-established the Canada Pipe & Steel Co. in 1907; organized Cluff Bros., Ltd., in 1909; organized the Cluff Manufacturing Co. in 1912; and the Security Storage Co. in 1913.

WILLIAM JAMES CLUFF.

Mr. Cluff married Ruby Sullivan, daughter of James Sullivan, Toronto, on February 12, 1907, his family consisting of two daughters. His clubs are the Albany, Toronto; the Commercial, London, Ont.; and his recreations, fishing and boating. In matters of religion, Mr. Cluff is Anglican. His residence is 151 Springhurst Avenue, Toronto.

Prices Per Lb. Unless Otherwise Stated.

and sheet bars are showing improvement, but producers are still taxed to the limit in supplying the demand. The nominal quotation for Bessemer billets and sheet bars is \$45, maker's mill, Pittsburgh, with open-hearth bars \$2 higher. In addition to the increasing demand for plates for army use, the requirements of shipbuilders show no abatement. The situation in sheets remains firm, the demand for blue annealed and specials being good. Galvanized are quiet, the return of spelter to a higher level having left the market a little unsettled. Galvanized sheets are quoted at \$4.25 Pittsburgh. The demand for wire products has quietened down, but mills are active in filling booked orders for future requirements. The local situation is unchanged, and dealers report prices as last week.

## Metals

The general situation is unchanged, business, if anything, having slowed up somewhat after recent activities. Copper is firm, but quiet, following heavy buying. Tin is unsteady, but inclined to become firmer. Spelter is quiet, following the recent good demand. Lead is again quiet, with an undertone of weakness. Antimony is steady, but uncertain.

**Copper.**—Insistent demand continues to keep the smelters and refiners working at very high pressure, and while the requirements for war purposes are very heavy, it is estimated that the greater portion of the mined metal is being absorbed by industries for domestic contracts. The future outlook, in this respect, is very encouraging, and it is expected that the present activity will continue for some time. The immediate demand has somewhat slackened, but it is anticipated that buying will be renewed shortly. Consumers have been taking an active interest of late, and are covering their early requirements. Present conditions point to a strong market, with sellers in control.

The London market has shown weakness in standard, and strength in electro, owing to increased demand for the latter, which shows an advance of £5, being quoted at £129 per ton. Owing to the recent heavy buying, both for export and home consumption, the New York market is very strong, quotations having advanced 1 cent on lake and 1¼ cents on electrolytic; the nominal price being 27½ cents for prime lake and 28¾ cents for electrolytic. Dealers here, while reporting an active market, are holding firm on quotations, which are 31 cents for lake and electro, and 30 cents for castings.

**Tin.**—The market retains the position it has held for some time and while there is apparently an added interest to the situation, that tends to keep firm prices, recent activities do not indicate that a buying movement is

## The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Que., Aug. 28, 1916.—Industrial conditions continue to reflect a gradually increasing development in domestic activity, in addition to that for war material and supplies. The shortage of labor, added to the increasing difficulty of procuring steel, will doubtless further affect prices of raw material; therefore, advances in some lines are not unlikely. Recent developments in the European situation will strengthen the cause of the Allies and increased activity is as a result looked for. The railroad situation in the United States is causing much uneasiness in commercial and industrial circles, affecting as it will, should a breach occur, the transporta-

tion of munitions and other needed supplies.

## Pig Iron

No change is noted in the general situation. Steel-making pig is as active as ever; the foundry demand also shows a slight improvement.

## Steel

With the holiday season drawing to a close, and the gradual return to cooler weather, the output from the mills and foundries is assuming capacity figures. The increased use of plates and short beams for trench supports and protections have resulted in a strong demand for these products. Deliveries of billets

imminent. The present situation is largely affected by the uncertainty that prevails regarding the future shipments of tin, which at any moment may be restricted owing to difficulty in obtaining permits. London reports a slightly easier market, while the New York situation is firm on a  $\frac{1}{8}$  cent advance, the nominal quotation being 38 $\frac{3}{4}$  cents per pound. The local situation is unchanged, with prices firm at 43 cents per pound.

**Spelter.**—The situation in spelter has quietened down after the recent activity, but the market remains comparatively firm. The buying which of late has been quite heavy, appears to have reduced the supply of metal held by second hands, and the feeling in the trade denotes an undertone that may ultimately develop into a stronger market. The London situation has shown improvement with an advance of £9 on spot and £2 on futures, quotations being £58 and £45 respectively. An advance of  $\frac{7}{8}$  cents on the New York market places the nominal quotation at 9 $\frac{1}{2}$  cents per pound. Local dealers, while realizing the recent activity and the present firm tendency, are content to retain their quotations at 14 cents per pound.

**Lead.**—The exceptionally heavy demand during the past two weeks has placed the lead situation on a much sounder basis, but it is not likely to show further strength; in fact, dealers are of the opinion that the market will again decline, as recent cables would tend to confirm reports that both Britain and Russia are well covered for the next six months at any rate. However, the domestic demand has been very good of late, which might indicate that consumers have allowed their supply to run low, resulting in the recent heavy inquiries. London reports a steady market with slight advances. Following the activity during the past two weeks, New York quotations are higher, the Trust price having advanced from 6 cents to 6 $\frac{1}{2}$  cents, while the outside interests are quoting 6 $\frac{3}{4}$  cents, an advance of  $\frac{3}{4}$  cents per pound. The demand here, while above the normal has not been sufficient for dealers to advance prices, which are unchanged at 8 $\frac{1}{2}$  cents per pound.

**Antimony.**—The improvement noted last week has eased off a little, but interest is still being shown, and consumers and dealers are apparently awaiting the trend of events before making further purchases. However, it is only on exceptional demand that this metal could return to a higher position, as the production has for many months greatly exceeded the requirement, even with many plants running under capacity. During the past two weeks the New

York quotation has shown an advance of 3 $\frac{1}{4}$  cents, the nominal price now being 13 $\frac{3}{4}$  cents per pound. Local dealers are quoting 17 cents, but anticipate an advance if the strength of the market continues.

**Aluminum.**—The market continues strong and very firm with quotations unchanged at 68 cents per pound.

#### Machine Tools and Supplies

Little change is noted in the machine tool situation. Shell making equipment is still in demand. The requirements of munition makers are becoming fewer every day, although there are still inquiries for standard or special machinery, but in single pieces. Deliveries on placed orders are much better, although manufacturers are feeling the effect of a shortage of help, which has been gradually increasing for the past two months. Small tool supplies are still in good demand, as these com-

#### CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion \$100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

modities are required continually and under present conditions, in large quantities.

#### Scrap

The situation in the old metal market is quiet, with dealers quoting previous prices. Increased activity is shown in steel-making scrap and copper, while brass and lead are much stronger.

**Toronto, Ont., Aug. 29.**—The most important event locally is the Canadian National Exhibition, which opened last Saturday. There are, as usual, many interesting exhibits, industrial and engineering, while a new feature has been introduced this year in the form of a display of complete shells of various calibres showing the method of manufacture from the raw materials to the finished article.

A statement recently issued by the Customs Department shows that the trade of Canada in the first four months of the fiscal year has increased by more than 100 per cent. July was a remarkably satisfactory month, the returns showing an increase of 141 per cent. The shipments of Canadian manufactured products in July were three times the

total for the corresponding month last year. Trade conditions in Canada are highly gratifying, and will help considerably in paying off the national indebtedness incurred owing to the war. The balance of trade is now exceptionally favorable.

#### Steel

The steel market is again very strong, and is unusually active for the time of the year. The enormous demand for steel for munitions and for other purposes connected with the war has resulted in a new buying movement in the United States and Canada. The mills have as much business booked as at any time before, and deliveries are getting as backward as ever, second quarter of 1917 delivery being about as early as can be promised now. Another upward movement has started in prices of steel products, the principal reasons being the shortage and increased cost of semi-finished material. The higher prices this week include an advance of 25c per 100 lbs. on steel bars, 25c per 100 lbs. on plates, and an increase of approximately 10 per cent. on boiler tubes. The situation as regards boiler tubes is perhaps tighter than in any other line, as the mills are sold up for eight to ten months on both locomotive and merchant tubes. Plates are also in heavy demand, particularly from the shipyards and boiler-makers. The leading mills have their entire output sold for this year, and have taken large contracts for delivery in first quarter and first half of 1917. Prices of wire products continue very firm, and an advance is looked for about the 1st of September. The wrought iron pipe situation is unchanged, but prices may advance. Following the departure of the hot weather, production has materially improved, although the shortage of labor is adversely affecting the situation. The demand for shell steel, however, is so pressing that the mills are making a big effort to increase the output as much as possible.

The market on sheets is firmer and quotations have advanced on black sheets, but blue annealed are unchanged. The hot weather seriously hampered mill operations; the output, therefore, was curtailed and deliveries were further delayed. Prices of galvanized sheets are lower, due to the recent declines in spelter, but the high level of black sheets will tend to steady the market.

The steel market in the United States continues very firm, with prices advancing on some products and deliveries getting more backward. There has been an increase in domestic buying, but consumers are still inclined to be cautious on account of the present high prices. Steel bars are unchanged at 2.60c and shapes at 2.50c, but plates have advanced and are now being quoted at 4c f.o.b. Pittsburgh. Open-hearth sheet bars

have declined \$2, and are now quoted at \$45 per ton Pittsburgh. Billets are unchanged, as are also Chicago warehouse prices.

### Pig Iron

The situation in the pig iron market is unchanged, but it is believed that the next movement is likely to affect prices favorably. The heavy production of steel assures a big demand for pig iron for the rest of the year, and prices may accordingly advance.

### Machine Tools

The active demand for munitions equipment continues, and local dealers report having received a number of interesting inquiries for machine tools for shell shops. Deliveries on large swing lathes are fairly satisfactory, although shipments are still being delayed in the local freight yards. American machine tool houses report that business booked by their agents in Great Britain is less desirable, due to the Order-in-Council, which calls for payment to the Government of 60 per cent. of the profits arising out of all business transacted in that country. One or two makers of grinders and shapers in the States have advanced their prices by approximately 10 per cent., and there is a possibility of an advance on planers in the near future.

### Supplies

Business in machine shop supplies continues brisk, with prices of practically all lines very firm. Although there are few price changes of importance to note this week, higher prices on some lines, particularly in steel and brass goods are anticipated. Linseed oil is lower at 84c per gallon for raw and 87c for boiled oil. Crude oil continues weak but there has been no further decline in gasoline, while lubricating and lighting oils are also unchanged. An advance of 5 per cent. has been made on Disston hand saws.

### Metals

The metal markets continue to display considerable activity and are firmer than they have been for some weeks. Although the markets generally are strong there have been no changes in prices with the exception of copper which has again advanced. Business locally continues very good for the time of the year and further improvement is anticipated. Metals for munitions are of course in good demand but ordinary business is keeping up well.

**Copper.**—The situation in the copper market is unchanged from last week and quotations are again a shade higher. Sales for November, and December are in large volume and export demand continues very heavy a great part, it is said, being for private consumers in the Allied Countries. The buying of the

last three weeks is rapidly cleaning up the supplies for the current year. Quotations are higher and nominal at 30c per pound.

**Tin.**—The situation in the tin market is the same as last week and quotations locally are unchanged although London is higher. The market is quiet but firm with no feature of importance to note. Tin is quoted at 44c per pound.

**Spelter.**—The market is quiet, and it is reported that there have been some second hand offers at concessions. Producers are now well sold ahead and are not anxious to sell. Quotations unchanged at 14c per pound.

**Lead.**—The market is less excited now than it was at the beginning of the week, prices being firmly maintained. The Trust price of 6.50c New York, is unchanged but independent prices are higher at 6.75c New York. The demand for lead is now heavy and producers are sold farther ahead than ever before. Local price 8½c per pound.

**Antimony.**—The market is now dull following the recent heavy buying movement, quotations being firm but unchanged at 18c per pound.

**Aluminum.**—The market is dull and quiet and the situation unchanged. Local price 68c per pound.

## U.S. INDUSTRIAL COMMISSION TO FRANCE

THE American Industrial Commission to visit France on the basis of unsolicited proposals made to the American Manufacturers' Export Association sailed therefor on Saturday, Aug. 23, on the steamship Lafayette. The object of the Commission is to make a technical investigation of present conditions in France looking to the reconstruction and reorganization of her communities and industries now and after the war. It is to determine also how the United States may contribute, as in largely increased purchases of French products. The French Government is to aid the Commission, partly through providing for transportation; the itinerary, will include some 25 cities. In the composition of the Commission as effort has been made to secure men of broad experience in some nine general classifications of industry and at the same time of a caliber calculated to lend dignity and standing to the enterprise. A printed report of the results of the commission's visit is promised.

W. W. Nicholas, assistant chairman Allis-Chalmers Mfg. Co., Inc., heads the commission as chairman. J. G. Butler, Jr., vice-president Brier Hill Steel Co., Youngstown, Ohio, and director of the Commercial National Bank, Youngstown, is scheduled to represent the iron and steel industry. Ambrose Swasey, Warn-

er & Swasey Co., Cleveland, is also numbered in the party. Among others of the commission, some fifteen in all, are the following; A. B. Farquhar, president A. B. Farquhar Co., York, Pa.; James E. Sague, former vice-president American Locomotive Co. and Public Service Commissioner, New York; F. J. LeMaistre, consultant, E. I. du Pont de Nemours & Co., Wilmington, Del.; John R. MacArthur, MacArthur Brothers Co., New York; Dr. C. O. Mailloux, consulting engineer, New York; E. A. Warren, vice-president Universal Winding Co., Boston; Samuel W. Fairchild, vice-president Fairchild Brothers & Foster, chemists, 76 Laight Street, New York; Noble Foster Hoggson, president Hoggson Brothers, Inc., contractors, New York; E. E. Russell, J. I. Case Threshing Machine Co., Racine, Wis., and George Burdett Ford, Geo. B. Post & Sons, architects, New York. E. V. Douglass, secretary American Manufacturers' Export Association, 160 Broadway, New York, and secretary of the Commission, arrived in France last week.

## LAKE SUPERIOR CORPORATION SUBSIDIARIES

AGGREGATE net earnings of the Lake Superior Corporation subsidiaries were \$3,503,471, last year, as compared with \$1,366,210 in the previous fiscal year. The larger income, however, did not go to the parent company, but remains in the hands of subsidiaries in the form of enlarged reserves and balances. The parent corporation's income consisted of interest on bonds of subsidiaries amounting to \$290,000 and other income of \$45,795, making a total of \$335,799, as against one of \$369,032 in the previous year. The disbursements out of income were somewhat less, being \$310,305, leaving a net of \$25,454. This added to the balance from last year leaves a sum of \$50,526, of which \$40,000 was applied to reserve for depreciation of securities and the balance carried forward.

### Algoma Steel

The amount realized by the Algoma Steel from last year's sales compared favorably with the record year, 1913-1914. The tonnage in each of the last three years was as follows—

	1913-14	1914-15	1915-16
Pig iron, tons	311,904	212,917	258,504
Steel rails, tons	325,680	174,536	*215,416
Merchant.			

tons . . . . . 15,576 8,903 . . . . .

\*This figure includes rails, shell, and merchant steel.

The water power which the company owned has been disposed of for \$1,000,000, which sum is held by trustees and is available for new construction.

## IMPORTANCE OF INCREASED PRODUCTION

W. L. HICHENS, chairman of Cammell, Laird & Co., Birkenhead, England, delivered an address recently on "The Importance of Increased Production," at the outset of which he said that, as a large employer of labor, all questions of labor and capital interested him more than anything else, save that of the war. The war had given us a new angle of vision in regard to many things. Before the war we lived in an age of individualism.

The watchwords of the nineteenth century had been self-realization, survival of the fittest, *laissez faire*, and the interests of the individual. Employers organized themselves into a federation, and working people organized themselves into trade unions, and both were there for the purpose of seeking their own in-

tense keenness, and for which they were prepared to lay down their lives if necessary. Many of us had begun to dream dreams and to picture to ourselves the possible use of that wider form of patriotism after the war. We are surprised to find how far away we have drifted from the old individualism of pre-war days.

Before the war many men made it their ideal to put together a competence so that at the earliest possible moment they could retire and live happily ever afterwards, and how many young men and women there were who thought it no shame to live a life of idleness if they could afford to do so. Now, however, the oldest 'dugout' in the country was rushing about to do his bit ashamed to be found idle when everybody had work to do. It is realized now that there is an unlimited demand for everything

was not an unlimited source of supply; fourth, and this was the most important of all, we could exchange goods exported for munitions and that was the most satisfactory way of achieving our object.

### Development of Export Trade

A very great deal had already been done in the way of increasing their exports. The latest figures showed that the exports of Great Britain in May, 1916, were worth £47,000,000; in May, 1915, they were £33,500,000; and in August, 1914, they were only £24,000,000. That was, of course, a very large and satisfactory increase, and if we would only go on increasing at the same rate our national standing financially would quickly show substantial improvement.

There were two ways in which we could do more. The first way was to increase Government organization, but Mr. Hichens did not think a very great

## Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

### BRAZIL

Bahia, British Consul.  
Rio de Janeiro, British Consul General.

### CHILE

Valparaiso, British Consul General.

### COLOMBIA

Bagota, British Consul General.

### ECUADOR

Quito, British Consul General.

### EGYPT

Alexandria, British Consul General.

### FRANCE

Havre, British Consul General.  
Marseilles, British Consul General.

### INDIA

Calcutta, Director General of Commercial Intelligence.

### ITALY

Genoa, British Consul General.  
Milan, British Consul.

### MEXICO

Mexico, British Consul General.

### NETHERLANDS

Amsterdam, British Consul.

### PANAMA

Colon, British Consul.  
Panama, British Vice-Consul.

### PERU

Lima, British Vice-Consul.

### PORTUGAL

Lisbon, British Consul.

### RUSSIA

Moscow, British Consul General.  
Petrograd, British Consul.  
Vladivostok, British Consul.  
Odessa, British Consul General.

### SPAIN

Barcelona, British Consul General.  
Madrid, British Consul.

### SWEDEN

Stockholm, British Consul.

### SWITZERLAND

Geneva, British Consul.

### URUGUAY

Monte Video, British Vice-Consul.

### VENEZUELA

Caracas, British Vice-Consul.

terests. That, of course, was not unnatural. The tendency was to think of their own interest as an individual first, and secondly of the interests of the class to which they belong. Politics was regarded as a game in which each section played for its own ends, and justice was supposed to reside in numbers.

The war came, however, and straightway some three million men sacrificed their lives for their country. The clouds seemed to lift, the horizon became extended, and all realized that patriotism was opposed to individualism.

### New Vision of Empire

The newer and wider outlook also applied in regard to their view of the Empire, and more particularly the Dominions. They realized that the life of the Empire was no mere sham, but was something that they realized with an in-

we can produce, and it was to be hoped that idea would not vanish when the war was over. It seemed that if it were a useful and essential thing for us to work to preserve our liberties, it would also be a valuable thing to work hard after the war for the sake of the happiness and welfare of the whole community.

To-day there was an unlimited demand for everything that could be produced. We wanted munitions for ourselves and for our Allies. We also wanted to produce as far as possible other things as well as munitions which could be exchanged abroad for something that would serve our immediate purpose. Munitions of war from abroad could be paid for in four different ways. First, by the selling of American Dollar Securities; second, by exporting gold; third, by raising loans with countries in which we wished to trade, although that

deal could be done in that way, because for his part he did not think the Government were very good organizers, and for another thing he did not think they had very good material to work upon. It was true they all had the defects of their qualities, but even so he preferred the trueulence and the steady independence which characterized the Englishmen to the subservience of a more docile people. If they had to pay the penalty of being lovers of freedom it was a price worth paying.

### The Shipping Problem

One of the things the Government could do was to direct with more practical thought the vital shipping interests of the country. Nearly a year ago he had tried to get a committee appointed of shipowners and Admiralty officials to organize the shipbuilding capacities of

this country. It was obvious that additional ships were badly wanted. It seemed quite clear that such a committee could see that every shipbuilding yard was occupied on a type of work most suited for it. That would have been a very great gain to the country. He also thought it would have been a very great gain if the merchant shipping was more standardized in this country, so that they might concentrate more on quantity than on quality. He was told that such a plan would be very difficult of application if not impossible. However, they would notice that quite recently a powerful body of shipping experts had formed themselves together to produce just these same standardized ships, which the Government had said were impossible.

He was still in hopes that the Government would do something in the matter, but for the moment they had to depend in the main on their own individual enterprise and effort. He felt confident that production could be largely increased, because it was still in them to make a very much bigger effort than had yet been done. Before the war, statistics showed them that two and a half times

as much work per working head was turned out in U.S.A., as compared with Great Britain. Of course there they had more labor-saving devices. The fault of this lay with British employers, who did not take the trouble to find out the best and newest appliances, because they felt that they could rely upon a cheap labor supply.

## Trade Gossip

**The Dominion Brake Shoe Co.** has increased its capital stock to \$200,000.

**The Pembroke Electric Light Co.,** of Pembroke, Ont., has increased its capital stock to \$250,000.

**The Burlington Steel Co.,** of Hamilton, Ont., has been awarded a contract for the reinforcing steel for the new Parliament Buildings at Ottawa.

**Montreal, Que.**—Controller Coté suggests that makers of turbine machinery be asked to examine the proposed aqueduct power scheme which will cost one

million dollars, before a consulting engineer is appointed.

**William Phillips,** European manager of the Canadian Northern, sailed for New York on the Saxonia last Saturday to assume duties in the head office at Toronto. Before leaving he received the thanks of the Lord Mayor of Bristol for the interest he had taken in that port's commercial shipping relations with Canada.

**Canadian Union of Municipalities.**—At the meeting of the Canadian Union of Municipalities, held at Montreal on August 23, the following officers were elected:—Honorary patron, Hon. Robert Rogers; honorary president, Mayor T. L. Church, Toronto; president, Ald. Leslie H. Boyd, K.C., Montreal; first vice-president, Mayor Stewart, Victoria, B.C. (where the next meeting of the union will be held); second vice-president, Mayor Stevenson, London; third vice-president, Mayor Hardie, Lethbridge; honorary secretary-treasurer, W. D. Lighthall, K.C., ex-Mayor of Westmount, Que.

# CANADIAN COMMERCIAL INTELLIGENCE SERVICE

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

## CANADIAN TRADE COMMISSIONERS.

## The Spirit of the Times

### *"Service and Co-operation"*

THE CANADIAN NATIONAL EXHIBITION—itself an expression of the Spirit of the Times—affords our Service Department an opportunity of demonstrating what our organization has achieved in the attainment of its ideal of Service and Co-operation

IN MACHINERY HALL we will show some of the principal tools used in the manufacture of 9.2 High Explosive Shells, such as Boring and Turning Lathes, Band Turning Lathes, Cutting-off Machines, etc., also a line of general purpose tools and equipment for the Tool Room consisting of tool room lathes, sensitive drills, etc. In our Woodworking Department we will show standard lines of band saws, planers, jointers and saw tables.

IN THE PROCESS BUILDING we will operate a toy-making plant, showing a number of interesting operations.

COME AND SEE US during the Big Show. Our representatives are willing and ready to give you the benefit of their experience without obligation. We are there to "Save and Serve."

IN OUR WAREROOMS on Front Street we have a large stock of wood and iron tools for every branch of industry. We are offering special inducements during the Exhibition. It will pay you to buy now.

# INDUSTRIAL <sup>A<sub>N</sub>D</sup> CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

## Engineering

**Montreal, Que.**—The Montreal Tramways Co. will build an addition to the St. Denis sub-station.

**Hamilton, Ont.**—The Acme Stamping & Tool Co. contemplate building an extension to their plant.

**Vancouver, B.C.**—The management of the Hotel Vancouver here have decided to instal a power plant.

**Niagara Falls, Ont.**—Work has been commenced on the erection of a plant for the Canadian Aloxite Co.

**London, Ont.**—The George White & Sons Co. will build an extension to their plant here to cost about \$12,000.

**Thetford Mines, Que.**—The foundry owned by La Fonderie de Thetford, Ltd., was recently destroyed by fire. Loss, \$75,000.

**Renfrew, Ont.**—The International Molybdenum Co. is planning an electrically operated refining plant here at a cost of \$150,000.

**London, Ont.**—London Rolling Mills Co., propose erecting an addition, to their plant to cost \$50,000. New machinery will be installed.

**Welland, Ont.**—The Canadian Steel Foundries, Ltd., have purchased a property here adjoining their plant in view of extensions in the future.

**Glenora, Ont.**—J. C. Wilson & Co., are in the market for an overhead traveling crane, hand power or electric driven, capacity 5 to 10 tons, to span from 40 to 50 feet.

**Toronto, Ont.**—The plans for the William Davies Co. new abattoir, have been prepared by Henshien & McLaren, of Chicago. The buildings will cost about \$200,000.

**Toronto, Ont.**—Lightning on Aug. 22 damaged the plant of the Interurban Electric Light Co., 215 Mavety Street, to the extent of about \$5,000. The damage was confined principally to one of the large dynamos.

**Toronto, Ont.**—Earl Grey School on Jones Avenue will be heated next winter with crude oil. An oil burning apparatus has been installed in the school. It is the first school in which this has been adopted, and if it is successful other

large schools and buildings may adopt this method of heating.

**New Westminster, B.C.**—Henry Schaafe of the Schaafe Machine Works, proposes to establish a modern machine shop and foundry here on the water front. The plans also include a ship repairing plant.

**New Westminster, B.C.**—The Saskatchewan Steel & Bridge Co., with plants at Moose Jaw and Medicine Hat, is planning to establish a plant on the coast with the ultimate intention of going into the steel shipbuilding business. A representative of the company recently visited this city with a view to selecting a suitable site.

**Niagara Falls, Ont.**—The Perfection Tire & Motor Co., manufacturers of automobile tires and mechanical rubber goods, will erect a factory in this city, providing the ratepayers ratify a by-law which will be presented to them in three weeks. The by-law provides that the city furnish the company with power at \$10 a h.p. for a period of ten years, also give the company a fixed assessment for this time.

**Brantford, Ont.**—In sixty days it is expected that the new factory of the Dominion Steel Products Co. will be completed and ready for operation. The building will be 90 by 370 feet and will be entirely constructed of steel and glass. The new factory will be in close proximity to the L. E. and N. Railway track and the contract for its erection has been let to the Austin Co., of Cleveland, Ohio. The cost will be in the neighborhood of \$65,000.

**New Westminster, B.C.**—A first-class steel shipbuilding plant and repair yard to be located here is the plan of John R. Duncan of the Vulcan Iron Works. It is proposed to establish at once a boiler shop and foundry and later on a steel shipbuilding plant. The plans call for an investment of \$150,000 at once and about \$200,000 more when the drydock is built. The equipment planned for the new establishment includes the heaviest plate rolls on the Pacific coast, weighing 55 tons and capable of handling steel plates one inch thick and 18 feet wide. The drydock will not be built while steel commands its present inflated price, although temporary marine ways may be built for proposed site adjoins the C. N. R. terminals in this city.

## General Industrial

**Port Stanley, Ont.**—It is proposed to erect a grain elevator here at a cost of \$100,000.

**Windsor Mills, Que.**—The Canada Paper Co. will build an extension to their mill here.

**Kitchener, Ont.**—The Canadian Consolidated Felt Co., propose building an addition to their factory.

**St. Jerome, Que.**—The Canadian Consolidated Rubber Co., of Montreal, will build an extension to their factory here.

**Toronto, Ont.**—Harry Webb & Co. will erect a factory and bakery at Kendal Avenue to cost \$78,000. A building permit has been issued.

**Brockville, Ont.**—A grist mill at Phillipsville owned by Reuben Haskins was burned on August 24. The loss is heavy as no insurance was carried.

**Drummondville, Que.**—Fire on August 20 destroyed the blending house and a large amount of powder at the Aetna Chemical Co. plant here. The damage is estimated at \$20,000.

**St. Thomas, Ont.**—It is understood that the Monarch Knitting Co. will remove all the machinery, etc., from the spinning department at the local factory to the St. Catharines factory.

**Hamilton, Ont.**—A new industry will probably be located here, a meeting having been held recently with the object of forming a \$100,000 company for the manufacture of plain and fancy biscuits.

**Stratford, Ont.**—At a special meeting of the city council on Saturday it was unanimously agreed that the city would accept the \$17,500 offered by the Kindel Bed Co., of Toronto, for the Kemp factory. P. E. Kroehler is president and general manager of the firm.

**Montreal, Que.**—Thompson & Norris, of Grand Falls, Mass., who have a branch here, propose building a factory on Delorimer Avenue, to cost about \$800,000. The Atlas Construction Co., of this city, are the general contractors.

**Vermilion, Alta.**—The Hayward Lumber Co., of this place, will proceed at once with the erection of a 30,000-bushel grain elevator on the C.N.R., also of a coal shed to have a capacity of 200 tons of coal; this building will be alongside

the elevator. The company will also erect an elevator at Kitscoty, both elevators having a capacity of about 30,000 bushels.

**Vancouver, B.C.**—The British Columbia Sugar Refinery has been granted a permit for the construction of an addition to its factory on Powell St.

**Guelph, Ont.**—A deal has been closed whereby the Partridge Rubber Co. will take over the business of the Standard Tire & Rubber Co., of this city, carry out the contracts, etc., and besides this will transfer the Montreal business to Guelph. The Montreal factory has been engaged in the manufacture of all sorts of small druggist rubber goods. The purchase price was about \$150,000.

## Electrical

**Arthur, Ont.**—The Town Council propose spending \$15,000 on a hydro-electric system.

**Scarborough Junction, Ont.**—At a meeting of Scarboro Township residents on Monday, it was unanimously decided to request the Township Council to submit a contract to the Hydro-Electric Commission for the extension of the Hydro into several parts of the municipality.

## Trade Gossip

**Montreal, Que.**—The Victoria Pier will be formally opened by H. R. H. the Duke of Connaught at the end of next month, on the occasion of the Duke's farewell visit to Montreal. This event will not only mark the completion of another important undertaking, but will be the forerunner of similar and extensive developments along all the harbor front.

**Canal Co. Raises Rates.**—The Manchester Ship Canal Co., which controls the port of Manchester, England, has announced that rates for discharging and loading vessels and for quay portorage, warehousing and storing in the open of merchandise and minerals, have been raised 12½ per cent. Ship canal tolls and wharfage and ship dues have been raised 5 per cent.

**Quebec Bridge.**—The final span of the Quebec bridge will be placed in position on September 11, weather permitting. At five a.m. the span will be floated from its present place on the bank of the river to the centre of the stream, under the bridge, and there raised and placed in position. The span weighs about four thousand tons and will be raised about 150 feet.

**The Port Hope Sanitary Mfg. Co.,** which was recently organized to take over the Standard Ideal Co. of Port Hope, Ont., is capitalized at \$1,250,000. The following directors have been appointed:—L. M. Wood, of J. & L. M. Wood, president; R. J. Cluff, president of the Cluff Manufacturing Co., vice-president; W. D. Ross, vice-president of the Nova Scotia Steel Co.; C. J. Cluff, president of the Canada Pipe & Steel Co., and M. L. Davies, vice-president of the Standard Chemical Co., directors.

**New record Ore Shipments.**—Great lakes ore carriers established a new record in the month of July, loading 4,750,157 tons, which exceeds by 242,581 tons the movement in June, which at that time was thought to have set a mark that could stand for a year. Up to Aug. 1 ore shipments for the season aggregated 29,365,724 tons, a gain of more than 5,000,000 tons over 1913, the banner year of the trade. Detroit vessel men predict that the year's movement will approximate 59,000,000 tons.

**C.P.R. Orders Cars**—The C.P.R. has ordered ten thousand new box cars, while at the same time it is keeping up its rail equipment by giving considerable orders to the Lake Superior Co., which now turns out as good rails as are manufactured anywhere on this continent. Thirty years ago the company had about 50 locomotives. To-day it has 3,000; it also has 100,000 freight cars, 2,500 first and second-class passenger cars, to which number it is always making additions.

**Canadian War Purchases.**—The purchasing department of the British War Office in Canada, organized under Lord Shaughnessy and employing systems and machinery of the C. P. R., had placed up to May 1, a total business in Canada for various general supplies, not including munitions, of \$13,000,000. Since then the business placed has amounted to over \$4,000,000, making a total of over \$17,000,000, more than \$7,000,000 of which represents transactions during the current year. About the most important business which has been received since last report covers additional orders for canned beans with pork to the extent of about 12,000,000 cans.

**To Make Munitions**—The St. Lawrence Bridge Co. has commenced the installation of about \$500,000 worth of machinery for the preliminary order for \$2,000,000, having been received from the Imperial Munitions Board. The company for the past few years has been concentrating upon construction work for the Quebec bridge. It is believed that in the course of a few months they will be one of the biggest producers of special war products in Canada. The St. Lawrence Bridge Company is controlled

**Blacklisted Firms' Insurance.** — The Controller of the British Foreign Trade Department has made public a license issued to British underwriters and insurance companies to carry into effect marine insurance contracts made with persons in the United States, notwithstanding such persons may be on the statutory blacklist, provided such contracts were made prior to these persons being placed on the list. According to a cablegram received by the Department of commerce from the American Consul-General at London, this license applies to any contract for marine insurance or insurance against fire, or any other risk of goods or merchandise during transit from the shipper's or manufacturer's warehouse until deposited in a warehouse on the termination of transit where any part of the routing is by sea.

**Pulp Shipments to U. S.** — Over two-thirds of the more than a billion pounds of wood pulp imported into the United States during the fiscal year ending June 30, 1916, and used in the manufacture of paper, came from Canada, according to a communication to the National Geographic Society, from John Oliver La Gorce, and issued by the Society as a bulletin in connection with the Government's inquiry into the increase in the cost of newspaper. The pulp importations for 1915-16 have been 180,000,000 pounds less than for the previous twelve months, yet the amount imported from Canada during the past year was 130,000,000 pounds in excess of her 1914-15 shipments. During the year just closed nearly 70 per cent. of the 1,135,000,000 pounds of U.S. imported pulp came from Canada, while most of the remaining 30 per cent. came from Norway and Sweden.

### Nickel Refining Company Formed.

The Canadian branch of the International Nickel Co., which is to undertake the manufacture of nickel in Canada, has been incorporated at Ottawa by letters patented under the name of the International Nickel Co., of Canada. The new company is empowered to produce, refine, smelt, etc., nickel, copper, iron, steel, cobalt and other minerals, and to occupy and develop lands and concessions relating to or containing nickel, copper, iron, etc. The incorporators of the new company are Britton Osler, K. C., Toronto; W. A. J. Case, and the usual number of office employees. A meeting of representatives of the Ontario Government will be held in Ottawa very shortly, when the plans of the company and the question of the selection of a site will be taken up. The new plant

**A TWO-IN-ONE  
WRENCH**

Here's the Bemis & Call Combination Pipe and Nut Wrench. It is made with forged steel bar; case hardened throughout. All parts are interchangeable and it will stand the roughest usage. If you're looking for a wrench that has a grip that won't slip, your search is ended right here.

**B. & C.  
Combination  
Wrench**

One wrench is  
better than two.

The time saved in handling one wrench instead of two will enable your employees to do more work. The general utility and all-round convenience of this combination has no equal.

Write for our complete catalog  
on wrenches.

**Bemis & Call**  
**Hardware & Tool Co.**  
Springfield, Mass., U.S.A.

will probably be built in units, and will provide a production of 12,000,000 to 15,000,000 pounds a year at the beginning.

**Trade Inquiries.**—The following inquiries relating to Canadian trade have been received by the Department of Trade and Commerce, Ottawa.

915.—Malleable Castings.—An Aberdeen firm will be glad to enter into correspondence with Canadian concerns prepared to quote for malleable castings cast to pattern.

922.—Kerosene or Petrol Engines.—A London firm of engineers wishes to purchase a number of kerosene or petrol engines; according to details obtainable from the Department, and invites offers, accompanied by full particulars, from Canadian manufacturers. The following is the specification given in their letter:—"The series of engines are required for electrical, agricultural and similar purposes, and should be of medium speed, not more than 1,400 to 1,500 in the small powers, and not lower than 600 in the larger sizes, the powers being from 1 horse-power up to 60 or 70, or even higher. Kerosene carbureters, etc., must be able to be fitted when required, otherwise petrol will be used, but should any engine answer to the above specification and yet be adapted only for petrol, we should still be pleased to have particulars. A separate price is required for bedplates, and blue-prints showing over-all dimensions should be submitted, together with delivery and prices."

The Tash-Orr Mines, Ltd., of Ontario, capitalized at \$3,000,000, has been incorporated at Ottawa by Baltimore, Md., business men to develop gold-mining claims at Tashota, Ont., a new field, Joseph Castelberg, is president; Gustav H. Nachman is vice-president; John L. Orn, of Buffalo, N.Y., is general manager. The mines are located in the Kowkash mining district, about 300 miles west of Cochrane, on the new Transcontinental Railroad. William F. Green has been engaged as engineer and works manager. A compressor, boiler, hoist and air drills have been installed and the company will immediately erect a twenty-stamp mill, which will constitute a unit for other stamps to follow.

**Granby Copper Output Increase.**—Copper production of the Granby Consolidated Mining, Smelters & Power Co., in July amounted to 4,368,846 lbs. This compares with 4,011,361 lbs. in June and 4,727,929 lbs. in May, which was the high record output.

Of last Month's total 3,092,274 lbs. were produced at Anyox, compared with 2,799,540 lbs. in June and 3,383,230 lbs.

**3 BIG REASONS  
WHY YOU NEED****PURO**

(MADE IN CANADA)

1. Puro Sanitary Drinking Fountains will give you a better water supply cheaper.
2. Puro will cut your water bills 15% to 35%.
3. PURO will safeguard the health of your employees and raise the standard of efficiency.

Are not these reasons enough? Then why hesitate longer? PURO equipment is not expensive—the first cost is low and the up-keep nothing. Easily attached: positively fool-proof. Let us make you a special proposition for a try-out in one of your departments. Write us now—to-day—giving us the number of men; an inquiry will cost you nothing.

## Personal

G. H. Duggan, vice-president of the Dominion Bridge Co., has been elected a director of the Royal Bank of Canada.

D. H. McDougall, general manager of the Dominion Steel Corporation, has been gazetted Honorary Colonel of the 187th Nova Scotia Highland Regiment.

William Hall representing Spear & Jackson, Ltd., Sheffield, England, is calling on the trade in Canada, en route to the far East.

Lieut. A. W. McKnight, late town engineer at Port Moody, B.C., has been killed in action. He was born 27 years ago at Owen Sound Ont.

Lawford Grant, sales manager of the Eugene F. Phillips Electrical Works, Montreal, has been appointed assistant general manager and assistant treasurer, with a seat on the board of directors.

C. J. Kavanagh, expert traffic director, of Chicago, and Superintendent of Toronto C. P. R. terminals, has been transferred to Montreal to take over the terminals there.

Fred Armstrong, a Toronto electrical contractor, has been elected a member of the board of the Port Hope Sanitary Manufacturing Co., and will in future act in the capacity of managing director.

Sir William Mackenzie, president and D. B. Hanna, vice-president of the C.N.R., have sailed from New York for London on the St. Paul. They are going to London in connection with C.N.R. affairs and expect to return in the first week of October.

Raymond McLaughlin, for 17 years in the offices of the Union Works of the Carnegie Steel Co. at Youngstown, Ohio, has been appointed secretary to Ward B. Perley, vice-president and general manager of the Canadian Steel Corporation at Ojibway, Canada.

C. H. Easson, manager of the Bank of Nova Scotia at Toronto, Ont., and formerly occupying the same position at

## METAL STAMPINGS

We are manufacturers of stamped parts for other manufacturers.

We do any kind of sheet metal stamping that you require. Our improved presses and plating plant enable us to produce the finest quality of work in a surprisingly short time.

We can finish steel stamping in Nickel, Brass or Copper.

Send us a sample order.

**W. H. BANFIELD & SONS**

372 Pape Avenue, Toronto, Can.

St. John, N.B., has resigned to accept the position of vice-president of Brown's Copper & Brass Rolling Mills, Ltd. This company has recently made large additions to the plant, which is located at New Toronto, Ont.

Earl McIntyre, for 17 years connected with the Republic Iron & Steel Co., Youngstown, Ohio, but who resigned recently to take the position of field engineer for the Canadian Steel Corporation at Ojibway, Canada, was presented with a chest of silver by his associates in the Republic Company offices.

Charles Pascoe, formerly metallurgist for the Canadian Steel Foundries, Ltd., and recently connected with the Thomas Davidson Mfg. Co., Montreal, as consulting metallurgist, has joined the Snyder Electric Furnace Co., Chicago, as metallurgist in that company's electric furnace research plant, at Clearing, Ill. Mr. Pascoe's work in connection with the Thomas Davidson Mfg. Co. had to do with the production of shell billets from a Snyder electric acid steel furnace, and his work in this connection has been peculiarly successful, as evidenced by the fact that approximately 90 per cent. of the billets passed inspection.

Dr. Walter Alexander Riddell, late Director of Social Surveys for the Methodist and Presbyterian Churches in Canada, has been appointed Superintendent of the new Trade and Labor Department of the Province of Ontario, created by the legislation of last session. The department includes several branches of the service which formerly acted independently—the Boiler Inspection Branch, Factories Inspection, Stationary Engineers and Labor Bureau. Dr. Riddell will probably commence work by a tour of the United States, and possibly Great Britain, in order to study the methods of employment bureaus, the organization of which will form an important part of the task of the new department. The new superintendent is a native of Stratford, Ont., and is 36 years old.

## Wood-Working

**Quebec, Que.**—The sawmill of Alex. Gagnon, of Chicoutimi, was destroyed by fire on August 22. The origin of the fire is unknown. The loss is estimated at about \$40,000. The insurance carried amounted to \$15,000.

**New Westminster, B.C.**—The Acorn Lumber & Shingle Co., which has recently been incorporated, is building a shingle mill here. The mill represents an investment of \$10,000, and will have a capacity of 100,000 shingles per day. M. D. Irvine is at the head of the new concern.

Steel Shell Forgings or Billets of any size or weight will move any distance or about curves upon our specially constructed Gravity Carriers and Incline or Horizontal power devices. No labor required.

**Canadian Mathews Gravity Carrier Co., Toronto**

### THEY SELL AND STAY SOLD

## KEYSEATER

for Milling Internal  
Keyseats

This tool is an attachment for the drilling machine, and is regularly made with straight shank for gripping in the drill chuck; taper shank can be had if desired. The tool is fitted with a high-speed steel rotary cutter for milling internal keyseats in one cut. To complete a keyseat it is only required to pass the tool through the hole just once. Innumerable inexpensive eccentric bushings are supplied whereby the tool may be bushed to meet any diameter above its own.

Write for Catalog C for full detail.

## Municipal

**Milton, Ont.**—The Town Council propose spending \$5,000 on additional fire equipment.

**Halifax, N.S.**—The City Council contemplate the construction of an abattoir at an estimated cost of \$25,000.

**New Toronto, Ont.**—By-law granting the Du Pont Fabrikoid Co. a fixed assessment, carried by the ratepayers 91 to 7 on August 19.

**Maillardville, B.C.**—A waterworks system will be installed here. F. L. Macpherson, engineer of Burnaby, B.C., has charge of the work.

**Swift Current, Sask.**—An additional unit will probably be installed in the municipal power plant Gas or steam power are being considered.

**Chatham, Ont.**—A by-law authorizing an expenditure of \$16,600 for new water mains to the sugar factory and the cemetery has been passed by the council.

**Winnipeg, Man.**—The Board of Control may decide to purchase a number of motor trucks for the scavenging and street cleaning departments.

**Lethbridge, Alta.**—By-law favoring a filtration system was carried by a vote of 382 to 76. Money by-law will now be submitted in order to finance the scheme.

**North Bay, Ont.**—A by-law will be submitted to the ratepayers shortly to authorize a bond guarantee to the Queen Hat Mfg. Co., who propose building a factory here.

**Peterborough, Ont.**—The city council propose installing an activated sludge sewage disposal system which will cost \$125,000. The Provincial Board of Health are dealing with the matter.

**Dunnville, Ont.**—A by-law will be submitted to the ratepayers on Sept. 25, to authorize a bond issue of \$53,000 to pay for the installation of a hydro-electric system.

**Hamilton, Ont.**—The city will engage Engineer Milne, of Toronto, to report on the proposed waterworks plant and send a deputation to Buffalo, Cleveland, Detroit and other lake port cities where modern waterworks systems have been installed.

**London, Ont.**—Tenders for a motor tractor have been received by the Board of Control. They will be passed along to the City Council at its next session, and in the meantime no figures will be published. Two types, front drive three-wheeled, and rear drive four-wheeled, have been offered.

We are qualified Tool, Die, Jig,  
Gauge and Fixture Makers.

## Railways--Bridges

**Vernon, B.C.**—The C.N.R. has started work upon its Kamloops-Kelowna line.

**Guelph, Ont.**—The Guelph Junction Railway Board has received an application from residents of Wellesley, in Waterloo county, to have a road extended to their town, a distance of nine miles from the county line.

## Tenders

**Winnipeg, Man.**—Tenders addressed to the Chairman, Board of Control, will be received up to September 7, for the manufacture and delivery of one 100-light, 2 circuit, high efficiency street lighting equipment complete with lamps. Instructions to bidders, specification and form of tender may be obtained at the office of the City Light and Power Department, 54 King Street.

## Contracts Awarded

**The Canadian Fairbanks-Morse Co.,** Toronto, have been awarded a contract for the pumps for the Ridgeway, Ont., waterworks.

**Pembroke, Ont.**—The contract for the new sub-station which the Pembroke Electric Light Co. is preparing to erect here has been awarded to Markus & Co.

**Edmonton, Alta.**—The E. M. Nesbitt Co., of Edmonton, has received the contract for erecting a machine shop and storehouse here for the C. N. R., at a cost of \$51,100.

## New Incorporations

**The Colonial Knitting Co.** has been incorporated at Ottawa with a capital of \$100,000, to manufacture knitted goods of all kinds at Elmira, Ont. Incorporators are Conrad Steele, W. W. Cleg-horn and A. Werner, all of Elmira, Ont.

**National Bronze, Iron & Engineering Works, Ltd.,** has been incorporated at Ottawa with a capital of \$750,000 to carry on the business of mechanical and electrical engineers at Montreal. Incorporators: L. A. David, J. S. Lamarre and E. C. Baker, all of Montreal.

# Here's the Whole Story of The Dictaphone

Both Ends of It.

### YOUR END OF IT—

You start dictating the minute you are ready—no waiting for anybody. You keep at it steadily or off and on, as you feel like. Full speed or as slow as you want. Correct yourself or repeat as often as you care to. In the meantime your typist is typewriting or doing other work—no part of her time is required for note-taking. If you have much dictation at a time, she has a lot of letters already written before you are through dictating.

### YOUR TYPIST'S END OF IT—

She hears your words. She gets what you say; no deciphering shorthand notes of what you said. She does not have to stop and wait every time you stop and think. She controls the dictation—she can make you repeat forty times without embarrassment to herself or annoyance to you. She dodges the nerve strain of taking shorthand notes, and the eye strain of "making them out." She gets through her work quicker, easier; writes better letters and more of them—and has time for other work. She writes your letters once, on the typewriter.

### THE MONEY SIDE OF IT—

You save at least a third on the cost of every letter. Certainly that isn't the least important feature of dictating to the Dictaphone.

Our booklet, "How One Man Saved Money," mailed on request. Write to

# THE NATIONAL STEEL CAR COMPANY LIMITED

## PLANT AND PRODUCT

PANORAMIC VIEW OF CAR SHOPS AT HAMILTON INDICATING EXTENT OF GROUND OCCUPIED AND LAYOUT OF BUILDINGS.

*The development of Canada's agricultural and mineral resources, and the broadening of the scope and multiplication of her manufacturing activities, are largely, if not altogether dependent, on the railroad mileage available; not main line altogether, important of course as that is, but particularly as to the main line feeders or branch lines. Next in importance to mileage is rolling stock—locomotives and cars. The accompanying article features a plant and equipment specially designed to produce the latter, and although of comparatively recent establishment, it will be seen to have embraced an opportunity and turned it to account.*

### Staff Article

ON the tenth day of September, nineteen hundred and twelve, several carloads of construction material arrived on a stretch of land on the eastern outskirts of the city of Hamilton, in the Province of Ontario, Canada. Such an occurrence has taken place on many occasions throughout the country and to the casual observer at that time, the incident was probably neither more nor less interesting than hundreds of other similar incidents. If the observer could have foreseen the extensive plant which was to arise on the surrounding land, and realized that within 4½ months the shipment of finished railroad cars would be an accomplished fact, he would have been constrained to pay more than passing attention to the seemingly ordinary event of a few freight cars arriving on a piece of vacant ground.

The land referred to is situated at the

eastern end of Burlington bay, on the southern foreshore of that inlet and less than 30 minutes ride on the city cars

naturally and being of rectangular shape is admirably adapted for the specific purpose of the plant erected on it.

GATE HOUSE AND EMPLOYMENT OFFICE AT ENTRANCE TO GROUNDS.

from the Canadian Pacific or Grand Trunk Railway depots. It has an area of almost 58 acres, being 800 ft. wide and 3,150 ft. long. It is quite level

### Inception of the Company

Incorporated on July 11, 1912, the National Steel Car Co. was organized by a group of prominent Canadian capitalists to undertake the manufacture of all types of steam, electric and street railway passenger and freight car equipment. Taking place as it did when car works were being rushed for deliveries, the inception of the business was attended by some delay in obtaining the desired amount of trained help. Fully 90 per cent. of the workmen were recruited from the ranks of the local inhabitants and as it was necessary to train them in the art of car building, the desired state of efficiency was not obtained so quickly as it otherwise might have been.

Under these circumstances, therefore, the feat of erecting and equipping shops, organizing a force and making shipment of completed cars on Jan. 31, 1913, less than five months from the breaking of ground is deserving of more than passing remark.

### General Features of Plant

The plant consists of two large buildings which contain the equipment for

WOOD AND STEEL STOCK YARDS WITH GANTRY CRANE IN FOREGROUND.

MAIN OFFICE BUILDING.

accomplishing the principal manufacturing operations, while several buildings are provided for various purposes such as office buildings, storage, hospital and works offices. The two main buildings referred to are situated north and south of each other the northern one being known as the main shop in which are located the steel and woodworking plants. This building is of steel construction of the monitor type and consists of three bays, two of which are 75 feet, and one 50 ft. in width. The walls are built of hollow fireproof tile for a height of eight feet above ground, and are of continuous steel sash above.

#### Reception of Raw Material

In strict conformity with modern practice, the equipment is laid out so that movement of the work is in one direction only, not in the buildings alone, but in the plant as a whole. When raw material is received by rail, it is immediately deposited in the northern end of the grounds. Here are the steel and

VIEW OF STOCK YARD FROM SOUTH.

lumber yards where immense quantities of steel shapes, wheels, shafts, and thousands of feet of lumber are held in readiness for consumption.

Much of the lumber is stored in piles, where it is subject to natural seasoning, while material required for early use is passed through a dry kiln and thence to the dry kiln storage.

The dry kiln is 100 ft. long by 60 ft. wide, and contains five tracks, a traverser being provided to enable trucks from the lumber storage to be run right in without trans-

ferring the material from one truck to another. The kiln was designed and erected by L. Moore Dry Kiln Co., Jacksonville, Fla., and is heated by steam, the walls being of fireproof hollow tile.

After treatment in the kiln, the lumber is transferred to the dry kiln storage, from which it is transferred by overhead traveling crane to the planing mill department. This crane passes over the steel yard and can be observed in several of the photographs. It has a capacity of 10 tons with a span of 60 ft., and the runway on which it travels extends for a distance of 520 feet. By this arrangement heavy materials are quickly stored to the best advantage, and are

yet within easy access of the various departments in which they are to be used.

#### Car Construction

The work of producing cars may be divided into three main classifications, running gear, structural work and woodwork. The first includes the making of forgings, stampings, bolts, nuts, rivets, pins, hooks, chains and other similar details; also wheel boring, axle turning and preparation of various components ready for assembling into finished trucks. The second classification embraces the cutting off, marking, punching, shearing and drilling of plates, beams and sections from which the steel frame work of the car is to be fabricated. Lastly, the wood must be selected and machined to size in readiness for building into bodies of various types with a minimum of labor.

#### Co-ordination of Departments

Work of these three descriptions proceeds along parallel lines both practically as well as theoretically. At the northern end of the three bays referred to, raw material enters from the stock yards of which mention has been made.

VIEW OF POWER HOUSE WITH SILO FOR WOOD WASTE.

Rough bars and rods of many shapes enter the forge department in the 50 ft. bay. In the adjacent 75 ft. bay beams and shapes of all sorts which have been cut to length in the cutting off department now make their appearance, along with plates which are trimmed to various shapes and sizes, and have holes punched or drilled to suit different templates. In the other 75 ft. bay, planers, moulders, cutting off saws and drills are engaged on woodwork as mentioned. These three departments are each the starting point for work of one classification which gradually assumes a more complete form with each succeeding stage until merging with the other product it becomes a complete piece of rolling stock ready to be stencilled with weights, lengths and the several hieroglyphics which decorate the modern freight car.

### Forging Department

Forgings used on railway rolling stock are subject to severe treatment both from work and weather. Their proportions must be ample, their quality good, and their dimensions accurate. Drop hammers and bulldozers therefore form a large part of the equipment, while much of the medium and light welding and forging is done in power-driven hammers. The equipment is all modern and of the most suitable type for this class of work. Among the principal items may be mentioned 1-5,000 lb. Chambersburg steam drop hammer; 1-

BASIL MAGOR,  
Vice-President and General Manager.

3,000 lb. and 1-1,500 lb. Erie steam drop hammers; 3 Erie trimming presses, and 1 board hammer. Three Ajax bulldozers with independent motor drives and individual oil furnaces handle a large variety of hot stampings.

A feature of this department is a complete rivet making plant consisting of a

continuous Ajax machine driven by a 20 horse-power C. G. E. induction motor. In line with the machine is an oil-fired furnace of sufficient length to receive stock lengths of rod, the capacity of the furnace being such that the machine can be kept constantly supplied with hot rods.

The general forging equipment is capable of handling a large variety of work, and includes one 1,500-lb. Chambersburg steam hammer; one 200-lb. and two 100-lb. Bradley cushioned helve hammers, and one No. 11 Baudry power hammer.

### Drilling Department

Some of the work as done in the forging department is ready for use, but a considerable part requires both drilling and machining. Many of the smaller parts from the steel preparation department also require drilling, so that a considerable equipment has been provided for this purpose. Approximately twenty machines are engaged in this department, consisting mostly of medium-sized vertical drill presses, with such special machines as 1-6 and 1-5 spindle multiple drill, and 1 Bausch 15 spindle drill for special repetition work. A Lapointe broaching machine is also installed, this type of machine being particularly adapted for machining slots, oval and irregular holes of all descriptions.

### Machine Work

Owing to conditions existing during

VIEW OF FORGE SHOP, SHOWING BULLDOZER, STEAM HAMMER AND OTHER HEAVY EQUIPMENT.

STEEL PREPARATION DEPARTMENT, SHOWING LARGE TWIN CYLINDER HYDRAULIC PRESS, PUNCHING AND SHEARING MACHINES AND WORK IN PROGRESS.

the past two years, work of a much greater variety has been undertaken than was originally anticipated. Deviations from standard designs have involved a greater variety of equipment in the machine shop than would have been the case had the class of work remained of a more or less specialized nature. The

present machine shop which covers a floor space of about 50 ft. long by 75 ft. is being doubled in area. Approximately 50 tools are installed and these are being constantly added to. As the output of the plant during recent months has included such diverse products as steel sleeping cars and field kitchens,

passenger coaches and trench trucks, freight cars and ammunition wagons, the varied nature of the machine shop equipment has been of particular value in handling the constantly changing type of work.

Among the tools in this department are the following:

PLANING MILL WHERE LUMBER IS MACHINED TO SIZE AND SHAPE READY FOR USE IN CAR ERECTION DEPARTMENT.

One 36x36x144 Butler planer.  
 One 36x36x144 Pond planer.  
 One 24x24x120 Bertram planer.  
 Three Bertram slotters, 20, 24 and 28 inches.  
 One Putnam slotter.  
 Two Bertram shapers.  
 One C.M.C. shaper.  
 One Besley horizontal disc grinder.  
 One Jones & Lamson turret lathe.  
 One Gisholt turret lathe.  
 Nine engine lathes.  
 Four C.M.C. axle lathes.  
 One C.M.C. car wheel boring mill.  
 One Bertram wheel boring mill.  
 One Newton horizontal milling machine.  
 Five plain milling machines.  
 Two Becker vertical milling machines.  
 One B. & S. No. 4 universal milling machine with constant speed drive.  
 Two Ford Smith grinding stands.  
 Where considerable repetition work is necessary, modern quantity production

in the centre bay. The various structural parts entering into the trucks have meantime been prepared in the steel preparation department where the steel underframes have also been fabricated.

#### Steel Preparation Department

A cutting-off shop is arranged close to the steel yard where preparatory operations are done on joists, beams, angles, etc., so that when they enter the centre bay of the main shop, the work of marking off holes, punching, drilling, riveting, etc., can proceed right away. The cutting off shop contains four Lea-Simplex cold saws, which handle the structural sections, while two Cleveland automatics are engaged on bar stock, turning out shackle bolts, clevis pins and similar parts.

The steel preparation as already mentioned proceeds parallel with the forge and machine shop work. It occupies the north half of the bay which is 680 ft. in

R. D. Wood Co., is specially designed for car shop use, and is really two machines in one. It is similar in general construction to the hydraulic forging presses now so extensively used in shell manufacture, but has twin cylinders which can be operated simultaneously. When this is done the upper platens are bolted together so as to accommodate dies of considerable dimensions for pressing such articles as bolsters, side frames, etc. A large oil-fired furnace of suitable capacity is located to the left of this press, where the material to be stamped is heated up to the proper temperature.

#### Steel Erection and Truck Department

Having traveled along the 300 odd feet of this department, the various parts arrive at the truck department where riveting, bolting, and assembling proceeds. Pneumatic equipment is largely in evidence here, Cleveland hammers,

WHEEL SHOP WHERE WHEELS AND AXLES ARE ASSEMBLED READY FOR TRUCKS.

methods are made full use of, especially on milling operations on small links, rod ends, pins and other similar parts entering into the construction of trucks.

#### Wheel Shop

Wheels and axles are received in the rough state and require to be bored and turned before they can be assembled with the truck frames. One of the photographs shows the wheel shop in a state of normal activity, the pressing of the wheels on to the axles being done in a Bertram car wheel press, observable in the left foreground of the picture.

All of the parts which have originated in the forge or machine shops are now ready to build into trucks which is done

length, the south half being devoted to truck erection where the product already referred to awaits the arrival of the structural parts. The machinery consists principally of punches and shears, among them being the product of both Canadian and American tool builders. Bertram, C. M. C. and Brown-Boggs are well represented, the latter having a 10 ft. shear, while the two former makers have both punches and shears, many of the punches being of the multiple type. One large machine is equipped for punching numerous holes simultaneously at any part of a 10 ft. length of beam.

In the illustration of this department will be observed a large hydraulic press. This machine which was supplied by the

drills, and similar apparatus being liberally provided.

It is now that the numerous parts begin to take on a semblance to familiar objects. Wheels are placed on tracks, and truck frames, springs, brake gear, etc., assume their various positions with wonderful rapidity until, with the placing of the main frame on the trucks, the car is ready to receive the particular type of body required to render it fit for service.

#### Wood Preparation

The planing mill department has meanwhile been preparing the lumber out of which the body is to be built. Here again design and organization

make themselves apparent. Planers, moulders and matchers deliver the work in gradually advanced stages, being then cut to length in continuous feed cut-off saws, after which holes are drilled, morticed and recessed, special shapes formed and all work done so that the various pieces of lumber fit together exactly when they are built up on the underframe of the car.

This department is equipped with a Sheldons exhaust system for removing all dust, shavings and similar refuse which are drawn through suction pipes by a powerful fan, and then forced a considerable distance through an overhead pipe to a silo on top of the power house, being then distributed to the furnaces of the boilers underneath.

The work done in the wood car department marks the practical completion of the car with the exception of painting. During the building of the body much detail work is done involving the use of purchased supplies, fittings, etc., and in order to have these promptly available

an extensive stores department is provided. All of the rivets, bolts and nuts used in construction are made in the plant, and the stocking of these alone calls for considerable binnage.

CARS IN COURSE OF ERECTION IN FREIGHT CAR ERECTION DEPARTMENT.

Much of the lighter material and many detail parts and fittings are not suitable for manufacture in a plant of this description, and with the production of passenger coaches and sleeping cars, the variety and extent of material which it is necessary to carry in stock assume large proportions. The extent of

the stores department will be understood when it is stated that upwards of twenty employees, including a stores office staff, are required to handle, receive and deliver the goods passing through. Upholstering material, hair springs, carpets, lighting fixtures, lavatory and toilet fittings, and special equipment to meet different specifications, all have to be secured within stated periods, and kept in proper condition for ultimate use on the finished product.

#### Passenger Rolling Stock

The production of modern passenger cars, whether of steel or wood, calls for considerable detail work involving skilled labor of a high order including cabinet making, upholstering, painting and decorating. A special planing mill for performing machine work on car details exclusively forms part of the south building. It is completely equipped with morticers, band saw, sander, and drills and prepares all of the parts made of rare and expensive woods which fur-

NARROW GAUGE TRENCH TRUCKS IN COURSE OF CONSTRUCTION FOR A EUROPEAN GOVERNMENT.

nish and decorate the interiors of modern rolling stock. Here the bulkier parts are reduced to size and prepared as far as possible for the final fitting in the car. The smaller pieces and the making of seats, cushions, etc., is carried on in the cabinet department on the floor above. Window frames, sashes, seats, springs, etc., are here in profusion in all stages of completion. A special drying kiln and two veneer presses are installed on this floor so that close attention can be given to this important work.

Meantime, the car bodies having been mounted on their trucks, the cars are moved into part of the south building where they are furnished with the details from the cabinet shop, and have all wiring for lights, plumbing fixtures, floors, carpets and other interior furnishings installed, the painting, varnishing and decorating being performed at such times as suit the progress of the work.

#### All-Steel Passenger Cars

The first all-steel sleeping car made in Canada has recently been completed in these works and has aroused considerable interest among railway officials as well as the general public. In these cars which have been built for the Government lines first consideration has been given to safety, comfort and

appearance. The only inflammable materials in the car of this type are the berth curtains and the bedding, and as the steel construction renders it impervious to fire from outside causes, fire

battery being maintained in a charged condition by a generator driven from one of the axles.

#### Interior Features

Internally the car is very attractive.

The general treatment of walls, seat ends and other exposed parts is Cuban mahogany, while the seats are upholstered in the finest of green plush. The floor is of flexolith, a fire-proof material resembling concrete, this in turn being covered with rubber matting. Wilton carpet is laid on the aisle and in the drawing rooms and salons. Ten compartments are provided, consisting of a lower and an upper berth. Lavatory accommodation is particularly taste-

ful, the ladies' lavatory being finished in white tiles on the floors and walls, with exceptionally large mirrors of finest French plate.

The mens' smoking room is finished in Koko wood, large lounge seats providing the maximum of comfort during long trips. Two very fine drawing rooms are included in the design, one being in Vermilion finish and the other in Old English.

#### Motor Truck Production

The extension of the company's activities in the direction of motor truck construction was but a natural sequence to

FINISHING FREIGHT CAR BODIES IN ERECTION DEPARTMENT.

cannot seriously endanger the occupants. Other important safety features are the locking attachment which eliminates any possibility of the trucks being detached from the body of the car, and brakes of the clasp type which provide twice the braking power of the ordinary type.

The exterior of the car of which we reproduce two views, presents a handsome appearance, designed in the conventional type, and finished in the standard dark olive green of the Canadian Government Railways. An electric storage battery for lighting purposes is located midway between the trucks, the

VIEW IN PASSENGER CAR ERECTION DEPARTMENT.

CRATING DEPARTMENT FOR FOREIGN SHIPMENTS.

the successful accomplishment of railroad car building. The public demand for satisfactory equipment in this line has had a steady and persistent growth which along with the growing experience of truck users pointed to the fact that a high-grade truck of moderate initial cost, built in a suitable range of sizes, and backed by satisfactory service, was the logical result to be expected from such a firm as this. The result of much careful preparation and investigation is apparent in the line of trucks offered.

Five designs are made, the capacities being, 1, 1½, 2, 3½ and 5 tons respectively. Each model is a complete product in itself. Simplicity, accessibility and maximum service are the dominant features of all. That the efforts of the engineering staff toward this end have not been in vain will be gathered from a brief description of the trucks. Moderate speed motors of ample power are

employed. They are all of the four-cylinder, water-cooled type with cylin-

motor, but in the larger sizes it is of separate construction, both engine and transmission having three-point suspension. Power from the transmission is carried to the worm-driven rear axle by a tubular propellor shaft of drawn steel, having a universal joint at each end. The transmission gears are very large and are of heat-treated chrome nickel steel, a right-hand gear-shifting lever operating in a selective quadrant giving three speeds forward and one reverse.

#### Worm Drive and Other Features

All sizes of trucks are equipped with worm-driven, full-floating axles of the David Brown type, in which the worm is mounted on top of the worm wheel, and the worm wheel and differential are mounted as a unit in a cast-steel carrier, bolted in position in the centre housing of the axle. This permits the ready disassembling of the worm, worm wheel, and differential, without removing the axle from under the truck, the weight of

ALL STEEL SLEEPING CAR FOR CANADIAN GOVERNMENT RAILWAYS.

ders cast in pairs. In the 1-ton size the transmission forms a unit with the

the vehicle and load being carried on heavy steel tubes, forced under hydraulic pressure into cast-steel housings.

A feature of interest to truck owners is the provision of a speed governor which automatically controls the maximum speed by means of a centrifugal governor, which forms an integral part of the motor, being enclosed in the motor casting and sealed. Where opportunity renders it desirable, the power from the motor may be utilized for such purposes as operating dump bodies, winches, cranes and so forth, by means of a suitable attachment designed for this purpose. Tungsten steel valves insure freedom from valve grinding while the pistons, which are tapered to provide for expansion, are fitted with compound, leak-proof piston rings. A high-tension, waterproof magneto with dual system of ignition, and a high-grade automatic carburetor indicate the efforts which have been made to insure freedom from operating trouble.

EUROPEAN TYPE OF FOUR-WHEELED FREIGHT CAR.

### Welding Shop

No development of modern science has been overlooked regarding its suitability for adoption as a manufacturing process, and it is not surprising, therefore, to find that oxy-acetylene welding has been adopted on a considerable scale as a manufacturing process. The rapidity and economy with which odd-shaped pieces can be produced with this apparatus have displaced much expensive forging work previously done by hand in the smiths' shop. Cutting stock of all sections to odd shapes, welding sheets, plates, straps and stampings to form standard items of car construction can be performed with an ease and economy previously unknown. The equipment in this department is of Canadian design and manufacture, the entire outfit being supplied by L'Air Liquid Society. Two large generators for producing acetylene gas from carbide are installed in a well-ventilated building about 75 ft. square, which

END VIEW OF STEEL SLEEPING CAR.

provides ample room for ten or twelve operators to work in comfort. Part of the floor space is set apart for finishing, bench and grinder equipment being provided for three operators for dressing off rough edges, etc.

### Power Plant

The supply of power for a plant of this nature is a problem of considerable importance, and has been solved by utilizing both steam and electricity wherever either of these systems proved better adapted than the other. The majority of the metal working machines are of large size and widely separated, being thus suited for individual drive by electric motor, while steam hammers, kilns, heating system and hydraulic pumps provide a considerable load for the boiler installation. The power house equipment consists, therefore, principally of steam driven apparatus.

Hydraulic power is provided by 4 large Burnham compound pumps of the

PRODUCTS FOR RAIL, ROAD AND TRENCH PURPOSES BUILT BY THE NATIONAL STEEL CAR CO.

outside end packed plunger type working at a pressure of 1,500 lb. per sq. in. in conjunction with a 90 ton Wood accumulator. These pumps are served by a jet condenser supplied with water by a regular type of Burnham pump.

Pneumatic power is supplied by a

photographic. The company maintains its own emergency hospital and ambulance. Stretchers are located within a minute's distance of any part of the plant while notices in three foreign languages are posted in conspicuous positions where danger may arise. All

mentally. Permanent arrangements by the company resulted in the establishment of an up-to-date department including a fully equipped kitchen.

The nature and extent of the operations constantly proceeding will be apparent from the illustrations throughout the article and the thoughtful reader will well understand that the value of such an organisation is not to be computed in dollars and cents nor by the quantity of the output but because of the high standard of achievement which

cross compound steam driven compressor built by Canadian Rand. Corliss valve gear is provided on the steam cylinders which are 18 in. and 34 in. dia., which are coupled to the high and low pressure air cylinders respectively, these being 20 in. and 32 in. dia., with a common stroke of 36 in.

#### Boiler Equipment

The boiler equipment consists of five water tube boilers, three of those being built by the Erie City Iron Works and of 250 horse-power each. The other two are by Goldie McCulloch Co., and of 300 horse-power capacity each. Burnham feed pumps, and a Cochrane feed water heater complete the equipment. A conspicuous feature of the power house illustrations is the large exhaust pipe which carries shavings and other refuse into a silo well above the boilers from whence the fuel descends by gravity into the furnaces.

The office building is of utilitarian design and construction, being built of hollow tile, and furnished to suit the requirements of the different departments. Included in this building are the mechanical engineering, purchasing, accounting and treasury, executive and

BIRD'S-EYE VIEW OF WORKS, SHOWING PRINCIPAL FEATURES REFERRED TO IN ARTICLE.

minor injuries however slight are given immediate attention and that such efforts are fruitful is shown by the record of the past two years when as many as 2,000 men have been employed. During this period, no fatal accidents occurred, no legs were broken, one arm was amputated and two arms broken.

In the basement of the main office building is situated the restaurant for office staff and foreman. The necessity for such a facility was rendered evident by the distance of the plant from suitable establishments at which the employees could secure meals, also because experience has shown that makeshift efforts by the employees on their own behalf are not always maintained at a sufficiently high standard to conduce to the best state of efficiency physically or

it holds forth as an industrial establishment set upon the broadest and firmest of foundations.

The personnel of the men who are guiding its affairs is substantial evidence that sound judgment and invaluable experience will, in the future as in the past, continue to characterize the policy of the company in all its affairs. The Board of Directors as at present constituted consists of the following gentlemen:—

President. — Sir John M. Gibson, K.C.M.G.

Mortimer B. Davis, President Imperial Tobacco Co., of Canada.

First Vice-President.—Basil Magor.

Second Vice-President.—Sir Henry M. Pellatt, C.V.O.

W. G. Ross, Chairman Montreal Harbour Commissioners.

C. H. Cahan, K.C., President Western Canada Power Co., Montreal.

R. J. Magor, Managing Director, Magor Car Co., New York.

J. J. Scott, K.C., Hamilton.

Murray H. Coggeshall, Coggeshall and Hicks, New York.

W. Kirkpatrick Brice, New York.

Samuel King, London, Ont.

NORTH SIDE OF SHOPS, WITH EMERGENCY HOSPITAL AND PRIVATE BOAT DOCK IN FOREGROUND.

# The Mineral Production of British Columbia During 1915

By E. A. Haggren, M.E. \*

*The data here given details the salient features of the Annual Report of the Provincial Bureau of Mines for the year 1915, and incidentally constitutes the first authentic statement of the mineral production for that year. It will be observed that the aggregate output for 1915 approaches the high records of 1912 and 1913. A noteworthy development is that of the establishment of local refining plants for the treatment of copper and zinc ores.*

THE annual report of the Provincial Bureau of Mines for 1915 is one of the best that has been issued by that department. It gives the first authentic statement of the mineral production for the past year, which stands third highest in the mining records of the Province. The total production is stated at \$29,447,508, and was beaten in 1912, when the figures reached a total of \$32,440,800; also in 1913, when the production reached \$30,296,398. The figures are as follows for the year ending December 31, 1915:—

Mineral.	Quantity	Value	Increase over 1914	Decrease Under 1914
Gold, placer .....		\$ 770,000	\$ 15,000	
Gold lode, oz. ....	250,021	5,167,934	58,530	
Silver, oz. ....	3,366,506	1,588,991		\$ 287,745
Lead, lbs. ....	46,503,590	1,939,200	167,323	
Copper, lbs. ....	56,918,405	9,835,500	3,714,181	
Zinc, lbs. ....	12,982,440	1,460,524	1,114,390	
Coal, tons ....	1,611,129	5,638,952		699,433
Coke, tons ....	245,871	1,475,226	67,764	
Miscellaneous .....		1,571,181		1,281,736
Total .....		\$29,447,508	\$5,237,197	\$2,268,914

The net increase over the previous year is thus \$3,058,685, due mainly to the output of copper and the exceptionally high prices for that metal ruling during the latter part of the period. The remarkable increase was in zinc, the production of which increased nearly 100 per cent., while the selling price showed an increase of over 400 per cent. With the increase of copper production, gold and silver might have been expected to show a greater increase, as these metals always accompany copper in this country.

The decrease in coal consumption is due to the inroads of fuel oil, a condition which the increasing price of oil and the additional cost due to the new tariff will no longer permit to continue.

It is interesting to note that the mineral production of the Province has exceeded the half billion mark, \$516,270,253, to be exact. Of this amount gold accounts for \$160,803,053, of about 35 per cent. Coal accounts for \$156,928,640, or about 30 per cent. Copper ranks next with \$96,774,870, or about 18 per cent. Silver comes next to copper in importance, with \$39,298,273. Lead figures reach \$33,407,662. Building material production, involving bricks and building stone, is valued at \$25,398,282. Zinc production amounts, to \$3,659,473.

\*Editor, the Mining and Engineering Record.

### Placer Gold

The placer gold return for 1915 is the highest since 1907, and was mainly due to increases in Cariboo and Atlin, which two districts produced 90 per cent. of the total. Owing to the number of men out of work last summer there were more individual parties working than usual on the Fraser, Thompson and Quesnel Rivers. Atlin production is placed at \$377,000; Cariboo at \$215,000; Quesnel at \$85,000; East Kootenay, where for some years placer gold mining has been neg-

ligible, produced \$15,000, and Similkameen, Nicola and Vernon rose from \$3,000 to \$12,000; Nelson yielded \$1,000; Revelstoke, Trout Lake and Lardeau, \$2,000; Boundary and Yale, \$2,000; Yale, Ashcroft and Kamloops, \$10,000; Lillooet, \$8,000; the coast districts, including Vancouver Island, are credited with \$2,000.

### Lode Gold

Increased ore production in Boundary and Rossland and opening of new properties in Skeena and Omineca accounted for the increase in lode gold, in which the Coast and Nelson districts showed a decrease.

The lode gold production was not so great as in some previous years, the output having been nearly half a million more in 1913, \$150,000 more in 1912, \$35,000 more in 1910, and nearly \$100,000 more in 1908, so that lode gold mining is not making the progress it should. Rossland leads with 142,595 ozs., and Boundary ranks next with 87,870 ozs., mostly derived from the smelting of copper ores carrying gold. Nelson and the Coast districts show a falling off, the former of 6,000 ozs. Similkameen was the largest producer of free gold, the Hedley Gold Mining Co. output being 6,000 ozs. over previous years, and all valued at over \$900,000. This district, however, is not specially given credit for the foregoing production, it be-

### Silver Output

The silver production was the lowest in the last three years as regards quantity and the lowest in four previous years as regards value. This was the only metal which did not recover from the slump of prices following the declaration of war. The price was about 5c per oz. less than the previous year and about 10c. per oz. less than for 1913. Sloean produced 62.9 per cent. of the total and Fort Steele 14.3 per cent., the latter being almost entirely from the Sullivan mine. The following is the production of the various mining divisions: Sloean 1,812,550 ozs., Fort Steele 481,258 ozs., Ainsworth 289,565 ozs., Boundary 273,795 ozs., almost entirely as a by-product from the copper smelters; Skeena 175,179 ozs., Trail 159,584 ozs., almost entirely as a by-product of Rossland gold-copper ores; Omineca 79,155 ozs., Coast 66,033 ozs., mainly as a by-product of the copper ores from the Britannia mine; Trout Lake-Revelstoke 16,740 ozs., Nelson 9,405 ozs., mainly from Sheep Creek; and all other districts 3,242 ozs.

### Lead Production

This metal showed a falling off of 4,121,458 pounds as compared with previous years, but owing to the price being three-quarters of a cent. per pound more, the value was greater by \$167,323. Fort Steele division leads with 57 per cent. of the total production, mainly from the Sullivan mine. Sloean produced 32.10 per cent. of the total. The production of the various mining divisions was: Fort Steele, 26,582,050 pounds; Sloean, 14,925,345 pounds; Ainsworth, 3,436,184 pounds; Nelson, 967,775 pounds; Omineca, 249,279 pounds; all others, 342,957 pounds. The lead output was the lowest in the last

three years. This is due to the fact that the lead production is mainly from argentiferous galena, and owing to the low price of silver, most of the Slocan mines were shut down for the first half of last year.

#### Copper Shows Record

Copper was one of the two metals in which there is a record production for 1915, the amount being over 5,000,000 pounds greater than for 1912, the next highest year. The copper production of the province has doubled in the past fifteen years, and copper mining is making such rapid strides that the production should be doubled again within the next two years. The value was about \$1,500,000 greater than for 1906, when the high copper prices of that cycle reached their climax. The exceptionally large production last year was due to the enterprise of the Granby Consolidated Mining, Smelting & Power Co., which provided 66½ per cent. of the total production.

Great changes are taking place in the source of the copper output. Boundary production has fallen off 50 per cent. as compared with 1912, due to lessened ore production and reduced grade of ore. Rossland output has doubled. The output of the Coast districts has more than doubled, owing to the operation of the Granby Co. new mine and plant at Anyox, and the increased production of the Britannia. Yale-Kamloops districts are increasing in importance as copper producers, their output showing an increase of 850 per cent. in three years. Nelson produced only 51,941 pounds, as compared with 586,764 pounds in the previous year, and 815,126 pounds for 1913.

The Coast districts produced 60.65 per cent. of the total for 1915, and Boundary districts produced 30.5 per cent. Coast areas were also the richest in copper, averaging 38 pounds per ton, while Boundary ores averaged only 14 pounds, and Rossland ores only 13½ pounds copper per ton. The ores of the latter camp are, however, gold rather than copper ores.

The growing importance of British Columbia as a copper producing country is evident from the fact that for the past year the value of this metal alone was almost as much as that of all the other metals put together. At the present time Japan is the world's largest copper producer, next to the United States, but at the present rate of progress this province will, within the next two or three years, displace Japan as the world's second largest producer. The history of copper mining, too, is that it affords the most reliable and permanent of all classes of mining, so that the towns being established in connection with the copper camps can, as a rule, look forward to becoming practically permanent communities.

The question of the local refining of copper has attracted much attention during the past two years. Hitherto all copper produced here has been refined in the United States, the Boundary blister copper going to the Nichols refinery in New York State, and the copper from Trail smelter, the Britannia mine and the smaller mines shipping to Tacoma smelter, going to the copper refinery operated in conjunction therewith. The present year will see the copper refining industry established for the first time in British Columbia, a refinery to produce about ten tons of refined copper per day having been almost completed at Trail smelter.

#### Zinc Production

The zinc production of British Columbia is showing important strides, the amount for 1915 being about double that of 1913, while the increase over the 1914 output was 65 per cent., and about 50 per cent. over 1909, the previous high record year in zinc. The price, too, was about 160 per cent. better than the average due to the exceptional war demand. Two-thirds of the production was from the Slocan mines; 25 per cent. from Nelson division, and the rest from Ainsworth and East Kootenay.

The principal producers were: Standard Silver Lead, 3,778,857 pounds; H. B., on Sheep Creek, 2,387,514 pounds; Silverton Mines, 1,385,859 pounds; Zinton, on Sheep Creek, 739,695 pounds; Retallick Mine, Ainsworth, 576,000 pounds; Lucky Jim, 788,158 pounds; Rambler-Cariboo, 546,660 pounds.

Hitherto all the zinc ores produced in the Province had to be exported for treatment, mainly to the United States. The current year has seen the important addition to the metallurgical plants of British Columbia of a zinc refinery operated at the Trail smelter.

#### Other Metals

The only other metals of which there was any production were molybdenite and antimony. From the Molly group, on Lost Creek, south of Sheep Creek, in the Nelson district, there were shipped 24 tons averaging 12.26 per cent. molybdenite, and on this property are several thousand tons running from 2 per cent. to 4 per cent., which it will pay to mill, and ship the concentrate. The only other molybdenite property worked is at the Reil Camp, on Alice Arm, where a mill has been built, and shipments have been made to Seattle. Molybdenite, concentrated to a grade of between 85 per cent. to 90 per cent., brings from \$2,500 to \$3,000 a ton.

Antimony was another of the war metals that went skyrocketing in price to 55 cents per pound, though it is now back at the normal price of about 15 cents. This mineral is common in British Columbia, but only one property is reported to have made shipments last year, and that was the Alps-Alturas, on

the North Fork of Carpenter Creek, from which two cars were packed and shipped to Scotland, the content being 50 to 55 per cent. antimony.

#### Earthy Minerals

Building stone and brick show a heavy falling off, owing to the small amount of new construction going on. The output for the year being only about half that of recent years. Two new classes of deposits were developed and small shipments made. There were the hydromagnesite deposits at Atlin, owned and operated by Armstrong & Morrison, of Vancouver, from which about 70 tons were mined and shipped. There is likely to be an increasing demand for this mineral on account of the development of the pulp industry. The other mineral deposit worked is at the Bitter Lakes in the Similkameen, where Epsom Salts occur in nature. Three hundred tons were mined and shipped to New York.

#### Coal and Coke

The output of coal was the lowest in nine years. The coke output showed an increase of about 11,000 tons over 1914, but was still below the returns for 1912, 1913, 1909 and 1908. Vancouver Island produced more coal than the whole of the mines on the mainland put together. The respective production was: Vancouver Island, 1,020,942 tons; Mainland, 951,638 tons. Of the Mainland mines The Crows Nest produced 852,572 tons and Nicola and Similkameen 90,066 tons.

Of the coal production 361,451 tons went into the manufacture of coke for the smelters. Of 245,871 tons of coke produced, 5,450 tons were made at Union Bay and 240,421 tons by the Crows Nest Pass Coal Co. While the British Columbia demand for Vancouver Island coal fell off 17 per cent., exports to the United States increased.

#### C.P.R. AND CANADIAN TIMBER

THE Canadian Pacific Railroad has taken the lead in using Canadian wood in its car and hotel building. It conserves some 6,000,000 acres of timber limits, and aids in every possible way to make known this source of almost uncountable wealth—knowing that timber wealth always constitutes an eloquent appeal to the settler, prospector, or capitalist. The company has just made up some figures which show the timber wealth of the country, and these, at the present juncture, will not be without interest: Lumber, laths and shingles, \$67,500,000; firewood, \$60,500,000; pulpwood, \$15,500,000; posts and rails, \$9,500,000; crossties, \$9,000,000; square timber exported, \$400,000; cooperage, \$1,900,000; poles, \$700,000; logs exported, \$850,000; tanning material, \$22,000; round mining timber, \$500,000; miscellaneous exports, \$300,000; miscellaneous products, \$10,000,000.

# Montreal Locomotive Works Plant and Equipment.

## STAFF ARTICLE

*In addition to the locomotive building and repair plants connected with Canada's principal railroad corporations, outside enterprise, by close attention to and observation of possibilities, has proved itself a valuable adjunct, and has contributed in no small measure to the high degree transportation achievement which the former have to their credit, and to the outstripping of which their efforts and activities conspire. What is indicated in the foregoing is readily applicable to the Montreal Locomotive Works, Longue Point, Quebec.*

**T**HE Montreal Locomotive Works was incorporated under the Dominion Companies Act in June, 1902, and in March, 1904, the first locomotive built entirely in every detail in the company's works was delivered to the purchaser, the Toronto, Hamilton & Buffalo Railway Co.

The plant is situated about six miles north-east of the heart of the City of Montreal, between the Canadian Northern Railway on the Northwest and the St. Lawrence river on the southeast and is intersected by the Quebec turnpike which is an extension of Notre Dame street, one of the principal streets of Montreal. The property has an area of 68.1 English acres. A system of tracks connects the buildings with the railway mentioned, and through same with all the lines that radiate from Montreal. Tracks also run from the works down to the river front, where the Government has constructed a dock and basin for the accommodation of ocean steamships. It will be seen, therefore, that this company possesses every facility for the import of the raw material and export

of its finished product in any direction.

### Plant Layout

The layout of the plant, which comprises 25 buildings, was the result of a careful study of the problems involved, and is believed to be unique for compactness and minimum distances of handling from raw material to the finished product. One of the distinguishing features of the arrangement is that all the principal shops necessary for the production of a locomotive are included under one roof. Objections raised against this style have been:—

(1) A possible want of light. (2) Increased insurance; both of which have been met. Indeed, it is believed that no similar shop has been insured at a lower rate; the light shows for itself in the interior photographs. The main building is of structural steel framing, the columns being supported on iron pedestals which in turn stand on concrete base blocks. The side walls to a distance of four feet above the ground are of stone. At each column is a brick pilaster from the stone work to the roof, the space between the pilasters being largely of glass.

### Machine Shop

The main building consists of seven different departments—hammer shop, boiler shop, tank shop, foundry, machine shop, erecting shop and running shed. The machine shop is 600 feet long and 169 feet wide, with an adjoining annex 222 feet long and 136 feet wide. The machinery in the shop as well as throughout the whole plant is electrically operated, and a large majority of the tools are equipped with individual motor drives. Tools which require frequent change of speed are

EXTREME EAST END OF NORTH BAY OF MACHINE SHOP, SHOWING PORTION OF FRAME DRILLING AND SLOTTING DEPARTMENT.

SOUTH BAY OF MACHINE SHOP LOOKING EAST, SHOWING INDIVIDUAL MOTOR-DRIVEN MACHINES, TOGETHER WITH MOTOR-DRIVEN GROUPS.

driven by variable speed motors, thus avoiding the shifting of belts and the changing of gears when change of speed is required. This results in a great saving in time and energy on the part of the operator, thereby increasing the efficiency of the shop. The tool equipment throughout the entire shop is modern and is constantly being enlarged; a liberal policy being in force by which new tools and devices which tend to accelerate the output or decrease the cost of production are installed as soon as their merits have been established.

Among some of the special machinery are several four-head planers having a bed 55 feet long and a clearance between housings of 5 feet; two triple head frame slotters—each head separately driven, having a bed 50 feet 1 inch long and 61 inches wide, and capable of

BOILER SHOP, WEST BAY.

slotting six bar frames at one time; universal and plain milling machines with tables running from 60 to 193 inches in length; and wheel and tire boring mills having swings from 51 to 90 inches. This shop is served by eight electric traveling cranes, five being of 10 tons capacity each, one of 16 tons, and two of 20 tons each. A large number of fixed radial cranes serve each tool where required, thus obviating waiting for the traveling cranes.

#### Hammer Shop

At right angles to the machine shop and on a line with the western end of it is the hammer shop. This building is 380 ft. long by 86 ft. wide. It is equipped with two large 6,000 lb. steam hammers for heavy forgings. Besides these are a number of smaller hammers for blacksmith and drop forging work, bulldozers and bolt forging machines, as well as hydraulic presses. Several radial jib cranes, with a range of 360 degrees, and equipped with air hoists or

SMITH SHOP SHOWING PART OF DROP-FORGING FLOOR.

suitable chain blocks, are located at intervals along the centre of this department, and every facility is provided for the convenient and rapid handling of material and shop equipment.

#### Boiler Shop

Next to the hammer shop is the boiler shop 380 ft. long by 135 ft. wide. At the south end of the shop is a riveting tower 66 ft. high, 40 ft. wide and 65 ft. 6 in. long. The riveting tower contains one 17 ft. gap, 125 ton pressure hydraulic riveter, and one 10 ft. 6 in. gap, 80 ton pressure hydraulic riveter. This shop is equipped with the latest improved machinery, including a hydraulic flanging press capable of 450 tons pressure, served by an oil furnace with capacity sufficient to take any size sheet. There are also two large bending rolls, one 12 ft. 3 ins. between housings and the other 16 ft. 4 in. between housings: a plate planer and a number of large

punches and shearing machines. One of the main features of this shop is the plate drilling equipment consisting of several large radial drills having

long, served by two electric traveling cranes, one being of 20 tons capacity, and one of 150 tons capacity. This shop has eight erecting pits and one testing

single storey building 65 ft. wide by 98 ft. long.

### The Foundry

Southeast and alongside of the machine shop extension is the foundry 280 ft. long by 220 ft. wide, having two cupolas with capacities of 15 and 20 tons per hour respectively. It will be noticed that ample space is provided on either side of the units shown for additional cupolas. The hot air heating system is also clearly indicated, pipes extending down alongside each main column. At the north end of the moulding department for heavy castings is seen one of the hot air distributing units. A large fan operated by a small vertical engine draws its supply of heated air from the chamber at the right, which is provided with steam coils. The moulding floor occupies a space 280 ft. in length and 63 ft. in width, of which a space 42 ft. by 80 ft. is devoted to machine moulding. By referring to the illustrations it will be seen that all large moulding boxes are designed for their particular purpose. Both in this and in the small castings departments, the equipment is of modern and up-to-date design, every facility being provided, also labor-saving apparatus for the rapid and economic production of all classes of locomotive and grey iron castings. Two large ovens are located in the east end of the foundry for drying cylinder and other large cores, each oven being 8 ft. 6 in. wide, 10 ft high, and 34 ft. long, inside measurements. In addition, there are four core ovens, each 8 ft. 6 in. wide, 8 ft. 5 in. high and 23 ft. long, as well as two reel type ovens for small cores, each 60 in. by 70 in. Six overhead traveling cranes serve this department, there being two of 5 tons capacity each, three of 10 tons,

SMITH SHOP, LOOKING SOUTH.

special heads. All holes subjected to steam pressure are drilled instead of being punched. The several fires in the shop are served by fixed radial cranes. For traveling heavy pieces through the shop, cars are used on a centre track. This shop is also served by five electric traveling cranes, one of 10 tons capacity, one of 20 tons, one of 25 tons and two of 60 tons each. Alongside the boiler shop is the tank shop 380 ft. long by 66 ft. wide.

### Erecting Shop

Adjoining the machine shop is the erecting shop 182 ft. wide by 120 ft.

pit and thoroughfare, giving a capacity of nine to ten large locomotives in process of erection at one time. Three tracks run from the erecting shop into the running shed which is 123 ft. long by 65 ft. wide. This shop will hold nine large locomotives under steam at one time. Adjustable smoke jacks have been installed through which is induced by means of an exhaust fan the smoke from locomotives under immediate test.

The pattern and carpenter shops are together in a two-storey brick building 65 ft. wide by 111 ft. long. Back of this building is the pattern storage house, a

SMITH SHOP, LOOKING NORTH, SHOWING FORGING MACHINE FLOOR.

NORTH END OF BOILER SHOP SHOWING PART OF THE ELECTRICALLY-DRIVEN, HYDRO-PNEUMATIC DRILLS FOR DRILLING RIVET HOLES.

and one of 20 tons. The controlling cage in most cases is located at the middle of the crane, as this position permits the operator a clearer view of all sections of the floor, and offers increased facilities for locating the ladle and heavy moulding boxes. In addition to the travelling cranes, the heavy casting department is equipped with a number of wall cranes, one being located at every other main column. These swinging cranes are provided with one-ton Peerless chain blocks. Owing to the severe weather conditions prevailing in Montreal in winter, all foundry supplies are kept under cover in a large supply storage room adjacent to the main bay and convenient to the charging floor. Such materials as moulding sand, coke, pig iron and scrap are housed therein. The charging floor is served from the storage room by means of skips handled by a 10 ton electric traveling crane.

The various materials are taken as

required from the supply in the storage department, loaded into skips and ele-

NEW GREY IRON FOUNDRY, STORAGE BAY FOR RAW MATERIALS SHOWING CHARGING FLOOR UNDER RIGHT-HAND END OF TRAVELING CRANE.

vated to the extended section of the charging floor shown in the upper right hand corner of the storage bay. The skips, which are constructed of sheet steel and steel angle, are so designed that when placed on the tracks, the flanged edges prevent them from slipping when the load is discharged from the tilting platform located in front of the charging door of the cupola.

#### Power Plant

Owing to the abundance of hydro-electric power in the Province of Quebec, a large part of the electrical energy required is purchased, but a power-house is provided, conveniently situated for economical distribution to all the departments. The boiler equipment consists of six water-tube boilers of 250 horse-power, each fitted with superheaters, arranged in three batteries. The boilers have automatic underfeed

stokers and induced draft. Overhead are two coal hoppers, each of 20 tons capacity, from which pipes lead to the automatic stokers. The coal is hauled upon a trestle to the top of the building and dumped into a coal breaker from which it drops into the bins. The engine room equipment includes one cross-compound Corliss condensing engine of 600 horse-power belted to a 400-kilowatt generator; one 710 horse-power motor generator set; and three air compressors having a total capacity of 6,000 cubic feet per minute, which maintain an air line pressure of 100 lbs. per sq. inch distributed to all departments. There is also located in this building a 1,000 gallon per minute Underwriter fire pump.

#### Water Supply

The water supply for drinking purposes is taken from a drilled well 500 ft. in depth, and is distributed throughout the works by a steam-driven deep-well pump. All the roof drainage, the overflow from the condensers, hot-well,

EAST HALF OF SOUTH BAY, SHOWING NEW TRUCK AND CYLINDER SHOP.

etc., drain into a reservoir of 300,000 gallons capacity. On the river bank are located two 2-stage centrifugal pumps, each having a capacity of 600 gallons per minute, connected to the distribution mains and the reservoir. Ordinarily they keep the reservoir full, but in emergencies can pump direct into the fire-protection service. The 1,000 gallon Underwriter pump in the power-house takes its supply from this reservoir and distributes the water about the works. There is also a 50,000 gallon tank elevated on a steel tower 100 feet in height directly connected with the mains and upon which the sprinkler system depends for a steady supply and head. It should be noted that all of the shops are fully equipped with automatic sprinklers.

#### Locomotive Production

A complete system of gauges and templates is in force by which parts of locomotives of the same class are made in duplicate and interchangeable. The plant is equipped to build locomotives regardless of type or size. At present the works have a capacity of about 460

locomotives per year, the latter having an average weight of 200,000 pounds each. In addition to the locomotive out-

put this company also builds a rotary snow plow, which has a high reputation for handling deep snow.

#### SOME INTERESTING FIGURES

DURING the past year the C.P.R. received from passengers \$24,690,652; from freight, \$89,654,405; from sleeping cars, express, telegraphs, and miscellaneous, \$13,752,260.

The transportation expenses came to \$38,915,381; maintenance of way and structures, \$14,071,791; maintenance of equipment, \$16,695,955; traffic expenses, \$21,798,699; parlor and sleeping car expenses, \$990,410; expenses of lake and river steamers, \$829,811; general expenses, \$4,014,753; commercial telegraphs, \$1,339,161.

The number of passengers carried one mile was 1,255,561,198, as compared

NEW GREY IRON FOUNDRY, SOUTH END OF MACHINE MOLDING FLOOR.

ERECTING SHOP FROM WEST END, LOOKING EAST.

with 1,164,488,630 last year. Tons of freight carried one mile, 14,050,685,773. Last year the C.P.R. carried 126,909,828 bushels of grain; this year it carried 276,788,209 bushels.

With such an army of workers, the pension figures of the C.P.R. are always interesting. Last fiscal year there was \$240,222 distributed to retired employees all over the system. This money is forwarded in cheques to the place of residence. It comes as regular as clockwork. It costs the recipient nothing. There are, as the annual report just to hand shows, 60 on the pension rolls under 60 years of age; 445 between 60 and 70, and 329 over 70, making a total of 834 enjoying pensions. The amount which the company contributed during the last fiscal year was \$125,000. There is a balance of \$585,548 up to the end of the present fiscal year.

## HOW TO GET EXPORT TRADE

THE manufacturer who proposes to enter some sphere of export trade must at least have a general knowledge of the conditions under which same should be sought and catered for. He should be in a position to determine clearly what classes of buyers exist so as to choose definitely on which of them it will be best to concentrate his selling efforts. More than that, he must learn what different forms his selling efforts must take, and also what forms he must avoid, says the Exporter's Handbook.

### Concentration and Specialization

The manufacturer must make up his mind definitely, for good or ill, which branch of the export trade he will enter. It will be useless for him to think that he can safely snap up orders from any and every direction, attempting to supply all markets through all channels, yet concentrating on none. System, and a certain conservative adherence to the apparently arbitrary conditions which exist, are essential. The established order of things—call it a congerie of vested interests or what you like, cannot be defied with impunity, not only because those vested interests are powerful, but because they are the interests of every section of the shipping trade, and not merely of privileged groups or individuals, being based on vital business necessities, and not on selfish monopolistic grounds at all. The insistence on indents from the great colonial and other established markets going solely through the hands of merchant-shippers or commission buyers is a case in point.

### Organisation of Export Department

The manufacturer must decide to create a properly organised export department, to be run by an expert untroubled by considerations of home trade, and to have an equal call on the service of the factory with that exercised by the home sales department. Above all, the export department should be given full and constant consideration, and not treated in an opportunistic spirit as a mere adjunct or a non-essential speculation, to be pushed or neglected at convenience, or to be subservient to the exigencies of the home trade.

### Special Treatment Feature

The markets to be catered for must be definitely selected, and for sound reasons in each case. The world generally is not prepared to accept and adopt the standard requirements of any particular nationality product or products. Each market rightly insists, and will do so increasingly in the future, on having its own particular tastes and requirements specially catered for; therefore, a manufacturer will not be justified in allowing his export ambitions to

expand unduly on the strength of selling a good article. It is useless to say that what is good enough for the home trade ought to be in favour anywhere else in the world. The wise policy is to discover what overseas markets a particular firm's products are most suited for, and its facilities for production, most easily adaptable to, and to confine attention to those markets. Indeed, a sound rule for the beginner in export trade is to select one market only, and to work it thoroughly, not necessarily refusing shipper's orders for other destinations, but consistently directing the active catering and selling policy to the satisfaction of the chosen market. That is a system which can easily be extended as circumstances require, whereas to diffuse uninstructed energy over all markets, and to hit the mark in none, is a course of action which deliberately invites failure.

### Export Salesmanship

There is the *modus operandi* of export salesmanship to be studied. The indenter abroad must be discreetly canvassed without antagonising the home merchant and buying houses upon whom the financial responsibility for the business rests. This work, as has been shown, depends upon the employment of one or more various types of selling agents, and it is in the selection of and relations with, these that many manufacturers make their worst and most costly mistakes. Much patience and care must be exercised in finding the right firms or individuals and, indeed, the building up of a successful agency system abroad often involves a series of disappointing failures, though persistence always ends in a satisfactory and permanent appointment or appointments being made.

Further, the entire onus of showing results should not be thrown upon the agent when appointed. It is futile to expect him to create business if not vigorously and intelligently supported by his principals. He can do nothing unless he has the right goods to sell, and unless his customers can rely on having their representations, complaints and instructions to him promptly and properly attended to by the manufacturer with whose interests he has been entrusted. In fact special vigilance should be displayed by the manufacturer in seeing that the distant overseas representative is not ignored and neglected for the benefit of the firm's home travellers, who, being on the spot, can make their demands on the factory and dispatching room, more clamorous and insistent.

A keen and experienced representative is required in London, and probably in other centres, to get confirmation from

the shipping and buying houses of the largest possible percentage of the orders notified by the overseas representative, and also to be alert to pick up any open orders that may be on offer. It is a gross mistake to suppose, as so many firms appear to do, that an under-paid junior will do this work.

### Manufacturer's Personal Interest Vital

Finally it remains for the manufacturer himself to take a keen personal interest in his export business, to push it by advertising and other general means, to utilise to the full such official assistance as may be available, and at the earliest convenient moment to make a personal tour of investigation in the market or markets he is serving. It is an invariable experience that the appearance on the scene of operations of the principal of a manufacturing firm does more than anything else to stimulate and encourage agents, to consolidate relations with importers, and, not least important to bring about an intelligent and vitalised treatment of shipping orders in the factory and office after his return home. These in outline are the guiding principles to be followed in establishing an export connection that will be worth while.

## GRAND TRUNK PACIFIC BRIDGES

A FEATURE of the Grand Trunk Pacific Railroad is the series of splendid bridges on the line are on the prairie pert—65, to be exact. In other words, there are 5.4 miles of steel bridging on that vast stretch. Three of the largest bridge on the line are on the prairie section, these being South Saskatchewan Bridge at Saskatoon, 150 feet long and 71 feet high; Battle River Bridge, 5,410 feet long, including approaches, and 190 feet high; and Clover River Bridge, over the North Saskatchewan River, 1,653 feet long and 138 feet high. There are also three bridges on the mountain division, over 1,000 feet in length, namely, McLeod River Bridge, 1,055 feet long and 116 feet high; Kau Schiswap Crossing, 1,030 feet long and 190 feet high; Fraser River, Fourth Crossing, 2,650 feet long and 36 feet high.

The highest bridge on the system is that over Pembina River, 860 miles from Winnipeg, 208 feet high. The Fraser River is crossed four times, steel bridges being at miles 1073, 1189, 1233, and 1276 from Winnipeg. The roadbed on the system is 18 feet wide, with rails weighing 80 pounds per yard. The gradients through the mountains are almost as easy as the prairies themselves. With these outstanding features, the system is equipped to secure a remarkable degree of efficiency.

# NEW QUEBEC BRIDGE

## "MAKING ENDS MEET"

STAFF ARTICLE

*It will be noted from what follows that most elaborate detail arrangements have been made to ensure success in the operation now imminent of linking-up through its ultimate member the highway of steel which will connect the North and South shores of the St. Lawrence River just west of Quebec City. May wind and tide harmonize with the human element and thereby render less onerous the normally stupendous nature of the task.*

**T**HE Quebec Bridge, one of the greatest engineering feats of its kind in the history of bridge construction, is fast approaching successful completion. The placing of the centre span, which is expected to be one of the most interesting and important features in connection with the entire structure, is awaited with deep interest by the engineering fraternity the world over, the hoisting and connecting of this middle section being conceded as marking the culmination of engineering achievement in the spanning of marine highways.

During the season of 1915, the North shore truss was entirely completed, the false work removed, and the travelling crane dismantled and transported to the site where the centre or suspended span was to be erected. Simultaneously with the erection of the North shore cantilever arm, the South shore anchor arm was being put together. In order to insure accurate alignment of the two sections of the bridge, calculations and observations were taken at stated periods of construction: same constituting

essential factors in connection with this huge and world-unique undertaking.

### 1916 Operations.

During the winter months, the fabricated material for the suspended span was finished in the works of the St. Lawrence Bridge Co., who are the contractors for the construction and erection of the bridge. About the first of April, 1916, operations were started on the river arm of the South shore section, which was practically completed about the first of August. The actual working days were 92, about 27 days being lost from inclement weather, Sundays, and Legal Holidays. An average gang of 200 men was constantly employed during this period. The total weight of steel placed in position this season amounts to about 13,000 tons; which, with that contained in the suspended span, will total approximately 19,000 tons. Owing to the experience gained on the North shore section, the work this season has been accomplished in 25 per cent. less time than the corres-

ponding work of last year; as a result, erection has progressed so rapidly that the South shore section has been finished one month ahead of schedule time. Fig. 1 shows the South shore cantilever as it appeared on August 6, with the travelling crane still in position; it being used for the placing of the mooring frame and hoisting equipment.

For the past four or five weeks, workmen have been engaged in installing the mechanical equipment and other apparatus required for the floating of the span and the hoisting of same to its final position between the two cantilever trusses. While the date for floating the span has been arranged for September 11, the actual day on which the supreme operation will take place will depend largely, if not entirely, upon weather conditions. The St. Lawrence River, at the bridge site, has a current of six or eight miles an hour, and a twelve to sixteen foot tide, therefore it is essential, that a time be selected—at high tide, when the wind is not excessive; weather disturbances would naturally

APPEARANCE OF BRIDGE, NOVEMBER, 1915.

increase the already known contingencies of tide and current. The hour of proposed floating has been set for between four and five in the morning, at which time the tide is most favorable. This will also give a long day for the

as it appeared on July 25, just prior to completion. Fig. 3, taken on August 7, shows a large portion of the false work removed; the outer end of the span resting on the steel towers at either corner of the structure, with the pontoons being

placed in position. At the time of writing, the remaining false work has been taken out and preparations are almost completed in readiness for the supreme hour when the pontoons will be permitted to raise the structure from the four corner supports.

#### Pontoon Features

The pontoons, three of which will be placed at either end of the span, are 165 feet long, 32 feet wide, and have a depth of  $11\frac{1}{2}$  feet. These are so constructed that the air tight compartments can fill and empty of water with the rise and fall of the tide, but, when desired, can be entirely drained at low tide, and, when the valves—one for each compartment—are closed, the rising tide will cause the scows to take the weight of the span and elevate it from its meantime resting place. This operation, however, will not be accomplished until a definite time of floating has been de-

FIG. 1. SOUTH SHORE CANTILEVER, AUG. 6, 1916.

operation, and, in order to prevent interruption, the Department of Marine and Fisheries, Ottawa, have issued notices to the shipping interests, that river traffic will be suspended on that date.

#### Centre Span Construction

Work on the construction of the centre span, which has a length of 640 feet, a width of 88 feet, a height at the centre of 110 feet, and weighs approximately 5,500 tons floated, commenced about the middle of April of this year, and was completed during the latter part of July. The site chosen for building the span was at Sillery Cove, about three miles below the point at which the bridge is being erected. Following the construction of the temporary approach, the actual work on the span was started; the false work and flooring with the lower side members being placed in position as the crane travelled outward. The upper side and top members were erected as the crane returned to the shore end of the structure. Fig 2 shows the span

FIG. 3. OUTER END OF CENTRE SPAN SHOWING PONTOONS BEING PLACED IN POSITION.

FIG. 2. CENTRE SPAN, JULY 25, 1916.

cided on. When all final arrangements have been determined, tugs will be provided, to tow the floated structure to the middle of the stream.

The tugs however, will not be required to tow the central span up the river, as the flow of the incoming tide is considered sufficient to float the scows with the structure to its position at the bridge. The chief duty of the tugs will be to guide the suspended span during its passage up the river and to hold it stationary, while being secured to the mooring frames. It is this feature of the proceedings that necessitates moderate weather conditions for the successful locating of the span. The exposed area is so great that even a light wind would add greatly to the natural difficulties already mentioned. Once the floating structure is secured to the

mooring frames, one of which is shown suspended from the outer end of either truss, the danger from the various elements is largely eliminated, as the mooring device is so designed as to withstand the effects of the highest winds.

#### Raising the Centre Span

The method adopted for elevating the central span, from the pontoons to its

lower member of the supporting girder, being taken directly through the connecting pins when in a stationary position; and indirectly through the jack when the weight is being raised.

The working lift of the jacks is two feet. Three holes for the 12-inch diameter locking pins are located 24 inches apart in the special girders; the corresponding holes in the hanger chains being placed

ated by compressed air, with the addition of other possible contingencies.

#### Emergency Provisions

To provide for any emergency through the possible failure of any of the hydraulic jacks, etc., large screw jacks are located on the inner side of each supporting girder. These screw jacks, each 12 inches in diameter, are not used to facilitate the elevation of the suspended span, but are for the purpose of constant adjustment by hand to the increasing space, as each separate lifting operation progresses. As shown in the various illustrations, platforms are constructed adjacent to the link connections for the workmen operating the locking pins and emergency jacks.

#### Power Equipment

The hydraulic equipment, necessary for the operation of the lifting jacks is located at the outer end of each cantilever arm. The cylinders of the jacks

FIG. 4. NORTH SHORE CANTILEVER WITH CENTRE SPAN LIFTING APPARATUS AT OUTER END.

final position is by means of eight 1,000 ton hydraulic jacks, two of which are located at each corner of both cantilever arms and supported on specially designed girders hung from the upper chord of each main structure. On the lower end of these hangers there is a special fixed girder which contains two hydraulic jacks, the plungers of the latter pressing against the moveable girder located directly above. The arrangement of the mechanism is such that the lifting strain is always on the

six feet apart; this provides for a lift of 2 feet at each operation of the jacks. The hanger chains, made in thirty foot lengths, are composed of two plates 30 inches wide and  $2\frac{1}{4}$  inches thick. With calculations based on a start being made at full tide, the 70 cycles required to lift the span 140 feet are expected to take about 16 consecutive hours of actual operation. The exact time is, however, only problematical, as it is altogether dependable upon the speed at which the hydraulic pumps can be oper-

FIG. 5. HYDRAULIC PUMPS AND PIPE LINE TO LIFTING JACKS.

FIG. 6. JACKING GIRDERS, HANGER CHAINS AND LIFTING JACKS.

are made of steel castings 22 inches inside diameter, and an outside diameter of  $33\frac{1}{2}$  inches, with rams of chilled cast iron. The pumps are of direct acting plunger type, and are operated by compressed air, supplied by compressors located on the shore at either end of the main approach. The air is delivered to the pumps at a pressure of 100 lbs. per square inch; the pump cylinders are 18 inches in diameter, and the water plungers of 2 inches diameter. Pumps, jacks, and all piping connections have been tested to 5,000 pounds pressure, but the actual working pressure is not expected to exceed 4,000 pounds per square inch. The installation is so designed that a uniform pressure will be

maintained upon all four cylinders, to insure equalization of stress at the various points of support. Provision, however, is made by an ample installation of balanced valves in the pipe line to control any particular unit.

#### General Observation

When the suspended span is in position, the total weight of steel in the bridge will be approximately 65,000 tons, 55,000 tons being fabricated material. Owing to the climate conditions, and the wide range of temperature between mid-winter and midsummer, which is from 130 to 150 degrees F., about 30 inches has been allowed for expansion and contraction in the total length of the bridge.

It is difficult to conceive the magnitude of this great undertaking. To appreciate the many problems of design and construction, it is necessary to have viewed the various component parts while erection was proceeding.

The design, construction and erection of this bridge form one of the great

(chairman and chief engineer), Ralph Modjeska, and H. P. Borden. The St. Lawrence Bridge Co. are the contractors for the superstructure; George F. Porter, engineer of construction; W. B. Fortune, superintendent of erection; and S. P. Mitchell, consulting engineer of erection.

#### Observation Facilities.

Owing to the limited space on the bridge and the necessity of keeping that portion of the river in which the tugs will be operating clear of all vessels not engaged upon the work, no one will be allowed upon the bridge who is not engaged in the placing of the span, nor will any steamers, small boats, or other craft be allowed within a considerable distance of the span being floated until it is suspended from the links by which it will be hoisted.

There will be ample space open to the public close to the bridge on the South shore and on the North shore from about half a mile below the bridge as far as Sillery Cove, where the suspended span has been erected. All of these

can be made for a special train from Montreal to Quebec. Fuller details of the programme will be announced later.

#### OUT FOR WORLD MARKETS

THE outline plan for the National Trade and Commerce Convention of Canadian Business Men, called by Sir George Foster, Minister of Trade and Commerce, for October or November, has been prepared, and the Department is now communicating with Boards of Trade all over the Dominion asking them to appoint committees to give the matter consideration. Letters are being also sent to Canadians abroad requesting their co-operation in the work of the Convention, which involves serious consideration of the industrial and commercial problems with which Canada will be faced at the termination of the war.

The memorandum which has been prepared for submission to business men all over the Dominion preparatory to the conference, assumes two stand-

SKELETON VIEW OF QUEBEC BRIDGE, SHOWING PRINCIPAL DIMENSIONS.

engineering achievements of modern times, and the official opening of this imposing and wonderful structure, which will take place early in 1917, will mark the completion of the last link in an unbroken Canadian railroad highway, which will extend from ocean to ocean. A noteworthy feature of the work which reflects much credit upon the engineers in charge, has been the immunity from accident during erection. From the nature of the undertaking, many minor casualties were to be expected, but the number of fatalities has been surprisingly few; only one being recorded during the past season. A boatman has been kept constantly in the river, immediately below the bridge, for rescue purposes should necessity arise. The efforts of the company to provide comfortable and attractive camp life for the men, have met with deserved success, the special arrangements made having doubtless exerted a restraining and beneficial influence on the workmen in the matter of exercising more than ordinary care in the performance of their varied and hazardous duties.

The work has been carried out under the supervision of a Board of Engineers composed of Messrs. C. N. Monserrat

view points are, however, so far removed from the actual work that it will be impossible to see any of the details of the mechanism or more than the general operation of floating and hoisting. At the suggestion of the officers of the St. Lawrence Bridge Co., the Council of the Canadian Society of Civil Engineers has arranged a special excursion for the 8th and 9th of September, when all the arrangements will be completed, and when the members of the society will be afforded every opportunity to see the details of the arrangements and be given an explanation of the proposed operations.

It is felt that in this way those engineers who are resident in Quebec, or who can spend a few days there, will have a much better appreciation of the actual operations than if these were only seen from a distance for the first time, and that those engineers who are only able to spend a short time in Quebec will get an opportunity of examining the structure and the mechanism that would not be practicable if they were only there at the time it is being floated. The St. Lawrence Bridge Co. will provide transportation from Quebec to the site, and it is hoped that arrangements

points from which the problems before the business interests of the country may be studied. The first of these will take account of the various factors which enter into the upbuilding of trade, such as market opportunities at home and abroad, credit information and banking facilities, commercial training, transportation facilities, labor, immigration, industrial equipment, and the study of raw materials; and, secondly, the various class of goods to the production of which the country naturally or specifically lends itself. It is suggested that committees of business men be appointed and assigned to certain definite problems, developing same from each of these viewpoints.

The results of the silent victory of the British navy are voiced by Rutledge Rutherford, the American economist and writer, who has recently toured Germany. He says: "(German) shipping is paralyzed, and in all the harbors there are great ships—passenger boats and freighters—being devoured by rust. The great free port of Hamburg . . . looks like a city of the dead."

# New Station of the Canadian Pacific Railway at Quebec

By C. T. R.

*The management of the Canadian Pacific Railroad is nothing if not progressive. Whether in anticipating or grasping opportunity, and giving the latter practical application or scope, it matters little. The growth and development of this big institution has been spectacular in many ways, yet accomplishment has been secured with an absence of loud display. Betterment with regard to employees' welfare, modern, effective, and comfortable rolling stock, efficient public service, attractive en route and terminal buildings and equipment, indicate some outstanding factors which have contributed to the high international reputation of the system. The new terminal depot at Quebec enhances the latter still further.*

**T**HE new C.P.R. station at Quebec, which was declared open last month, by the Mayor of Quebec is a triumph of modern railway station construction, besides being admirably located at the corner of St. Paul and Henderson Street just north of the old station. The latter will be removed to make room for the plaza, 350 ft. by 285 ft., which will form an attractive foreground with a large grass plot planted with shrubs and a sixty-foot roadway, flanked by sidewalks, planting spaces, Lombardy poplars, ornamental lighting standards, and two ornamental flagpoles. There will be thus transformed a once ugly portion of the city to a beauty spot which will not only be appreciated by the residents of Quebec, but will give the visitor a favorable first impression of the city.

The station building, which consists of a central block with two wings, is a modern adaption of the old French Chateau Style of architecture and admirably harmonizes with and helps to perpetuate the quaintness and historic traditions of the city. The exterior is faced with Argenteuil granite, Descham-

which faces the plaza, is dominated by a central motif containing the main entrance and is flanked by two tourelles

the facade. The pediment over the clock bears the arms of the City of Quebec.

THE ATTRACTIVE AND SPACIOUS CONCOURSE.

and protected by a glass and iron marquise the full width of the sidewalk. Over the main entrance is a large

In plan, the building is L shaped, the main block being 142 ft. x 65 ft., the concourse wing extending along Henderson Street, 142 ft. x 65 ft., and the baggage and express wing parallel to St. Paul Street, 130 ft. x 44 ft. Entering the building through the 24 ft., wide main entrance and vestibule, one is agreeably impressed with the spacious, light, ticket lobby, 45 ft. wide x 65 ft. long, which rises to a height of 60 feet. This lobby is finished through the medium of grey tapestry brick walls with Lepanto marble base, faience cornices, cartouches and balustrades, and sloping mosaic ceiling with leaded glass ceiling lights, the rich colorings of the faience and leaded glass lending an attractive tone to the decorations. The faience clock dial set in the balustrade at the first floor level with its flanking lion and unicorn is a feature of the room.

On the right side of the ticket lobby are the information wicket, four ticket wickets, the entrance to the women's rest room, and the news stand. On the left, are the baggage and parcel checking counters, customs office, public telephone booths and telegraph counter, while the Transfer Company's office opens off the

ARCHITECTURAL FEATURES OF AND MAIN ENTRANCE TO NEW STATION.

bault limestone and Citadel brick, all local products, with steep, sloping, copper covered roofs. The main facade,

window, above which is an illuminated clock with a seventy-two inch dial, which forms one of the principal features of

entrance vestibule. Opposite the main entrance is a series of seven doors opening into the concourse.

### The Concourse

The concourse, 125 ft. long x 62 ft. wide, and 40 ft. high, is similarly finished with grey brick walls, having faience inserts, marble wainscot, faience cornices and tinted ceiling, while the huge iron trusses, elliptical in form, which support the roof, spring from ornamental faience cartouches. On the left side of the concourse three sets of gates open to the midway and track platforms. On either side of each gateway is a mechanical indicator which shows the track number, time and destination of the departing trains. A massive train bulletin board has been provided on which the time of arrival of all incoming trains will be posted, while glass-covered bulletin boards have been provided for special announcements and posters.

On the right hand side of the concourse is an exit to Henderson Street, while at each end is a handsome faience dial clock. Comfortable seats have been provided, as the concourse serves also as the main waiting room of the station. The men's smoking room and lavatories are located at the North or far end of the concourse wing. The women's rest room is attractively furnished with rugs, table, chairs, and couch, and is conveniently located and easily reached from both the ticket and lobby concourse. The smoking room and women's room are wainscotted with wood panelling and the lavatories with marble. A feature of the lavatories are the pay toilets and dressing rooms which are provided with all the accessories necessary for the comfort of the traveller and equipped with coin locks which automatically operate by the insertion of a ten-cent piece.

### Baggage and Express Arrangements

Ample accommodation is provided for handling the baggage and express matter in a separate wing which has a covered trucking platform on each side. Everything necessary for the comfort and convenience of the travelling public, as well as the efficient operation of the train service, has been installed. The second floor of the main building, which is reached by a stairway from the main entrance vestibule, is devoted principally to the Company's offices and a museum in which an interesting and instructive exhibit of Canada's natural re-

sources and intertwined. The ceiling light over the ticket lobby contains the provincial shields and a map of the North American continent showing the Canadian Pacific Railway lines from coast to coast. The large window over the main entrance, which helps to light the ticket lobby contains the arms of the seven great men of Canadian history, viz. —Montmagny, the first Governor of Canada—1636-1647; DeTraey, Viceroy of Canada—1665; Beauharnois, Governor of Canada—1726-1747; Montcalm and Wolfe, the famous French and English generals whose names are familiar to all;

EXPRESS AND BAGGAGE DEPARTMENT ACCOMMODATION.

sources will be open to the public. The office corridors and museums surround the ticket lobby and are separated therefrom by open arches and balustrades which afford a splendid view of the lobby as well as provide an abundance of light and air. Rooms for conductors and trainmen with stairway direct from the midway are also provided on this floor. The decorative scheme of the interior is simple and artistic. The motifs in the richly-colored faience depict and symbolize emblems of our national life, and the Tudor rose, shamrock, thistle, fleur de lys, dolphin and trident are freely

Frontenac, Governor of Canada—1672; and Talon, the first Intendant of New France—1665-1672.

### Materials of Construction

The building was designed by H. E. Prindle, architect, of Montreal, and erected by the Downing Cook Co. of Montreal, under the supervision of D. H. Mapes, Engineer of Buildings of the C.P.R. In the construction of the building, which rests on 430 concrete piles, 400 tons of structural steel, 2,000 yards of reinforced concrete, 400,000 common brick, 75,000 exterior face brick, 125,000 interior face brick, and 10,000 cubic feet of exterior cut-stone, were used. Local labor and materials have been employed wherever possible. The concrete pile foundations were driven by the McArthur Pedestal Pile Co.; the structural work was furnished and erected by the Eastern Canada Steel Co.; the exterior face brick were made by the Citadel Brick Co.; the granite came from the Argenteuil quarries and the limestone from the Deschambault quarries. The interior marble and terrazzo work was done by the Mississquoi Marble Co.; the ornamental iron by the Dominion Architectural Iron Works. The plumbing and heating were installed by Vandry and Matte, the electrical work by the L. K. Comstock Co., and the clocks by the Self Winding Clock Co.

The woodwork throughout, of which, however, there is but little, is

A CORNER OF THE WOMEN'S REST ROOM.

Canadian birch, the railway company having recently adopted the policy of using Canadian woods exclusively for the finish of its buildings and cars. While the Station is the dominating feature of the improvements made by the Canadian Pacific, notice should be taken of the new freight office building and sheds constructed north of the station last year, the new power house located just west of the station and the re-arrangement of the coach yard, all of which has been done on the same comprehensive sale as, and in keeping with, the station building. Quebec can well be proud of its new station, which in design, finish and appointments is second to none in Canada.

SKELTON PLAN OF STATION BUILDING AND RAILROAD TRACKS.

### The Opening Ceremony

A notable company, representative of the political, commercial and industrial life of Quebec Province, was present when the new station was formally opened, on August 10, by Mayor Lavigne. Before the actual ceremony took place, several hundred ladies and gentlemen gathered at the station and proceeded to inspect the same.

After luncheon had been partaken of, A. D. MacTier, general manager of the C.P.R., and chairman of the meeting, made a few remarks regarding the auspicious occasion. The growing business, he observed, demanded this new structure, which he knew would be acceptable to the Quebec people, and the company had always stood willing to meet the people of Quebec in every way. The station was a proof of the latter. He

asked the mayor to accept a silver key as a souvenir of the occasion, a souvenir which might be regarded as a link uniting the city to the company.

His Worship the Mayor, in formally declaring the station open, made a happy little speech, in which he referred to the energy and prescience of the C.P.R., which was always ready to be in advance of the times. It was incumbent that it should have the necessary facilities to handle the overseas business which now showed such promise of increase. The C.P.R. had not failed to take note of what was happening. It did not exist for sentiment, but for commercial considerations. Yet it had a long vision; it had patriotism; it

closer relations with the lower provinces, as there would be a direct connection across the continent. The Government had done much in the building of new wharves and docks on the river-front to facilitate trade, and he could assure them that everything possible would be done by the Government to aid in the success of Quebec, which was now a most progressive city, and had considerably added to its manufactures in the last few years.

J. Picard, ex-president of the Quebec Board of Trade, followed with some interesting remarks, referring to the difficulties and hardships of the early times in Quebec, when communications were crude and slight and people had to put up with privations they could not think of to-day. He made a vivid contrast between that time and the present and gave great credit to the C.P.R. for what it had done in the interval. Of course, there was the initiative and energy of the people to be considered. They were living in times when efficiency was the primary note in business, and when it was necessary to put the shoulder to the wheel, using every facility.

The concluding speech was made by Sir Lomer Gouin, Premier of the Province, who aroused enthusiasm by enumerating the activities of the C.P.R., and especially the large governmental action which resulted in the building of the Transcontinental.

F. L. Wanklyn, of the C.P.R. Executive, followed, with a few brief remarks appropriate to the occasion.

### Those Present.

Those present included: A. D. MacTier, general manager Canadian Pacific Railway, who presided; Mayor Lavigne and Madame Lavigne, Hon. T. Chase Casgrain, Hon. L. A. Taschereau, Minister of Quebec Public Works; Hon. N. Perodeau, M.L.C.; D. O. Lesperance, chairman of the Quebec Harbor Commission; Hon. Dr. J. D. Reid, Minister of Customs and Acting Minister of Railways; Madame Casgrain, Sir Lomer Gouin, Premier of Quebec, and Lady Gouin, Hon. J. C. Kaine, Hon. George McCorkill, F. L. Wanklyn, executive assistant to the president of the C.P.R.; A. W. Campbell, R. B. Fraser, Mr. and Mrs. H. E. Pringle, Montreal; Mr. and Mrs. Dowling Cook, T. B. Ross, W. M. Dobell, M. Baneroft, O. W. Bedard, vice-president of the Quebec Board of Trade; T. Levasseur, Jas Picard, representing the Quebec Board of Trade; A. O. Gravel, St. George Boswell, Rev. A. S. Love, Hon. J. B. Caron, Minister of Agriculture; Sir George Garneau, J. B. Chouinard, Capt. Emile Trudel, Capt. P. Hamel, G. Madden, Duncan Robertson, Col. H. H. McLean, Lt.-Col. Fages, Lt.-Col. Chabot, Lt.-Col. Lafferty, Lt.-Elliott, Hon. Sir F. X. Lemieux

had ambition, and it was not afraid of large things. He praised such men as Lord Shaughnessy, Mr. MacTier, and Mr. Wanklyn, who believed in doing things and were not timid about taking opportunity by the hand. He concluded: "Remember, the C.P.R. wants to make dividends, but it also wants to develop the country, and all concerned should be pleased with the outcome in this particular direction."

The Hon. J. D. Reid, Acting Minister of Railways and Canals, said he was delighted to notice that the business interest of the city and Province of Quebec were growing—that the Province was prosperous, and that the city was being provided with additional railway facilities. The Government had not been remiss in this matter. It had operated the Transcontinental, and when the bridge was finished there would be

Vol. XVI. SEPTEMBER 7, 1916 No. 10

### PAPER SHORTAGE AND COST EFFECTS

THE publishing business in Canada and elsewhere is facing a serious crisis. Since the first of the present year there has been a growing scarcity of paper and a corresponding advance all along the line in prices. During that period the best grades of paper—white coated, have gone up fifty per cent. A medium grade of coated paper which cost 6 cents per pound previously cannot now be bought for less than 9 cents; and the mills are dodging orders at any price. Super-calender paper which formerly sold at from \$4.35 to \$4.50 is now quoted anywhere from \$7.00 to \$8.25. Newsprint—the rough surfaced paper on which newspapers are printed—has advanced nearly fifty per cent. Many of the best grades of paper have been taken off the market altogether, the manufacturers finding it impossible to keep up the quality. There is, in fact, a very general depreciation in paper quality despite the staggering jump in prices, and, notwithstanding the latter, manufacturers are being compelled to refuse business or to defer shipments for long periods.

#### Eliminating Non-Essential Matter

This condition is operating in two directions in its bearing on the publishing business. It is forcing publishers to economize on paper in every conceivable way. They are finding it necessary to reduce the number of pages printed. Lavish supplements, containing features whose scope of appeal is limited, have had to be excised. "Extras" are put out only when the news really warrants it. Newspapers, magazines, class papers, are all concentrating on the important problem of printing the really essential matter in the least space and eliminating all non-essentials. In this one respect, the paper shortage will prove a blessing in disguise. Publishers are examining their mailing lists closely, cutting off unprofitable "exchanges" and "dead heads" and are doing everything in their power to economize in other similar directions. In these days of scarcity only the man who wants

his paper sufficiently and is willing and ready to pay for it promptly should get his copy.

#### Increased Subscription Rates

The situation is reacting in another direction. It is forcing publishers to raise their subscription rates; many newspapers and class publications have already done so. Subscription rates in Canada have, in the past, been hammered down to a more or less ridiculous minimum by strenuous competition, but now it is clearly impossible for publishers to continue to supply their product at such low prices in face of the sudden advance of paper cost.

The reader should bear the foregoing facts in mind. If he is inclined to complain when his favorite periodical comes to him a little thinner, and when his renewal notice quotes a higher figure, let him pause to consider that it is only by such measures that the publisher is able to continue to send him the paper at all.

### RAILROAD DEVELOPMENT AND ITS EQUIPMENT MANUFACTURE

THE present issue of Canadian Machinery features in its editorial contents in a more than usually comprehensive manner, the large place that railroad progress and development fill in making available Canada's agricultural and mineral wealth. Incidentally, there is given probably equal prominence to its kindred aspect—her commercial and industrial enterprise. Of our four leading articles, two of these deal specifically with manufacturing plants and their equipment for the production of railroad rolling stock—cars and locomotives of every type and for every service; a third demonstrates the stupendous nature of the work which has occasionally to be undertaken to enable the "laying of steel" where it will best serve a predetermined purpose, while a fourth gives unquestionable evidence that there must needs be adequate and modern terminal facilities if the en route equipment is to secure its proper measure of patronage—both freight and passenger.

#### Larger Business in Sight

The now imminent spanning of the St. Lawrence by what is known as the New Quebec Bridge, naturally claims the larger share of popular interest at the moment, because marking the culmination of a Canadian engineering achievement which will command world-wide repute. In view, however, of the already available and yet to be secured opportunities to manufacture for export trade, the reader cannot otherwise than be impressed with the idea that the locomotive and car building plants illustrated and described in this issue are admirably planned and equipped for such eventualities. As a result of the opening to traffic of the New Quebec Bridge early in 1917, there is sure to develop an increased demand for rolling stock, comprising locomotives and cars. That the National Steel Car Co., and the Montreal Locomotive Works are prepared to take care of a still further domestic requirement and at the same time that arising from sources abroad is, we think, a quite justifiable conclusion to be reached from a perusal of the data presented.

Thanksgiving Day has, by an Order in Council, been definitely fixed for Monday, October 9.

## INDUSTRIAL NOTABILITIES

**G**EORGE HERRICK DUGGAN, vice-president and general manager, Dominion Bridge Co., Montreal, Que.; chief engineer, St. Lawrence Bridge Co. (contractors for steel work, new Quebec Bridge); vice-president, Montreal Ammunition Co.; president, Dominion Copper Products Co.; director, Montreal Trust Co.; director, Hillcrest Collieries, Ltd.; director, Royal Bank of Canada; was born at Toronto Sept. 6, 1862, only son of the late John Duggan, Q.C., and Amelia (Tulloh) Duggan. He was educated at Upper Canada College and in the School of Practical Science, Toronto University (1883), taking the post-graduate course in 1884.

Entering on a business career by joining the engineering department of the C.P.R. during the year 1884, Mr. Duggan, in the interval right up to the present, has held not a few specially responsible as well as publicly prominent appointments with a number of leading Canadian engineering and allied corporations and enterprises. Enumeration of several of these follows: Engineering department Dominion Bridge Co., 1886-1901; chief engineer, 1891-1901; assistant to president and consulting engineer, Dominion Steel Co. and Dominion Coal Co., 1902-1903; second vice-president and general manager, Dominion Coal Co., 1904-10; present position since 1910.

GEORGE HERRICK DUGGAN.

He is a member, The Institution of Civil Engineers, England; member and president, Canadian Society of Civil Engineers; member American Society Civil Engineers; member Canadian Mining Institution (vice-president, 1906, councillor, 1911-1913); one of the founders Toronto and Royal St. Lawrence Yacht Clubs; amateur yacht designer, designed and sailed winners "Seawanaka" International Cup, 1896-1901; captain, Toronto Yacht Club, 1883-1884; commodore, Royal Cape Breton Yacht Squadron, 1905-1910; commodore, Royal St. Lawrence Yacht Club, 1889-1890; honorary commodore, 1915-1916.

He was awarded Royal Humane Society's Bronze Medal and Certificate, 1893. It has been said that "he carries as much sporting blood in him as can safely be carried by a man who must temper sport with business."

Mr. Duggan married Mildred Scarth, daughter of Pilans Stevenson, Montreal, October, 1888, there being two sons and one daughter of the union. One of his sons, H. S. Duggan, R.E., was killed in action Oct. 21, 1915. His clubs are the Mount Royal, St. James, Engineers, Forest and Stream, and University (Montreal); Royal Canadian Yacht (Toronto); Royal Cape Breton Yacht (Sydney); Royal St. Lawrence Yacht and Garrison (Quebec). In religion Mr. Duggan is Anglican. His residence is 120 McTavish Street, Montreal, Que.

Prices Per Lb. Unless Otherwise Stated.

changes, and the market is quiet pending the outcome of the present industrial unrest. The demands for all classes of steel and iron products is still heavy, and in many respects the requirements are greatly in excess of the supply. Local dealers report a quiet situation, but showing uneasiness over the labor situation.

## Metals

With the exception of copper, the metal situation is unchanged. The general market has been affected by the developments of the railroad strike, as embargoes have been placed upon many of the roads, which will continue until the situation warrants them being lifted. Copper has stiffened considerably, owing to the impending placing of large export orders. The demand for tin has become lighter. Spelter is showing another weak spell, with declining prices. Lead is very quiet. Antimony is dull and weak.

**Copper.**—The market at present is very firm, owing to the report that negotiations for large tonnage, on extended delivery, have been under consideration for some time. Actual contracts have not yet been made, as producers have been asking stiffer prices on the strength of this additional business, with the result that prospective buyers have temporarily withdrawn from the market. The situation is likewise being affected by the unsettled condition of transportation facilities. As most of the large consumers are well covered for immediate requirements, they can afford to await the outcome of the present crisis. London reports the standard situation a little easier, with a decline of £1 on spot and £2 on futures. Electro is stronger on a £1 advance. New York continues very firm, with market quotations nominal at 27½c for prime lake, 25½c for castings, and 28c for electrolytic; the latter showing a decline of ¼c per pound. Local dealers report a very firm market, with quotations unchanged at 31c for lake and electrolytic, and 30c for castings.

**Tin.**—No special developments are noted in the week's tin market, and the situation is practically unchanged. In the absence of heavy buying, stocks are accumulating and a weaker tendency is being shown. The London situation is unchanged, with a slight falling off in quotations on futures. The New York market is firm, showing a ½c advance, but little business is being done. The quotation this week is 38½c per pound. Local dealers have advanced their prices 1c, and are now quoting 44c per pound.

**Spelter.**—All efforts to place the spelter upon a better footing seem to have failed, as the fluctuations of the past four or five weeks have apparently shown that a return to its high position of a few months ago will be long delayed.

## The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

**Montreal, Que., Sept. 4, 1916.**—Industrial and commercial interests have been somewhat disturbed, owing to the unsettled condition arising out of the possible tie up of American railroads. The strike, if it should go into effect, would not only dislocate United States trade, but would seriously affect conditions in this country. The situation in the war zone is gradually assuming a stage where the future outlook is much more encouraging, although an early ending seems very improbable. Industrial conditions continue to indicate the prosperous condition of Canadian trade, with domestic activities showing continual improvement.

## Steel

The possibility of an extensive strike upon the railroads throughout the United States has placed the market in an unsettled condition, and efforts have been made to provide material for the steel mills to continue operations. If, however, the strike should materialize, which at the moment is still difficult to determine, it would place the producers in a serious position, as the supply of raw materials would soon become exhausted. The embargoes, placed on several roads, will not be lifted until some satisfactory settlement has been made between the contending parties. The past week has been featureless in regard to price

The demand, which of late has given rise to the expectation of renewed activity in spelter, has never continued long enough to indicate a return to former interest. The situation has, therefore, developed into one of apparent dullness, with dealers and consumers showing little interest in the market. London reports show a decline in spelter prices, spot having declined £6 and futures £2. New York, on a decline of  $\frac{3}{4}$ c, is quoting 84-5c per pound. Local dealers are still quoting 14c on a quiet market.

**Lead.**—No activity is shown in lead, and the market is very dull. Owing to the falling off in demand, the independents are inclined to lower their quotations. The trade is, however, awaiting the outcome of the labor situation, and nothing can be said until some understanding is arrived at. London is a little stronger, while New York is quiet, but firm. The situation here is practically unchanged, although dealers are asking 8 $\frac{3}{4}$ c, an advance of  $\frac{1}{4}$ c per pound.

**Antimony.**—The market at present is very dull and the demand very light. In an effort to make sales, some dealers are reported to have offered metal at low figures, but the only result has been to weaken the general market. The reported orders for additional shrapnel have created a little interest, and indications point to a steadier market. A decline of  $1\frac{1}{4}$ c on the New York market has lowered the quotation to 12 $\frac{1}{2}$ c. The situation here is quiet and unchanged, with prices firm at 17c per pound.

**Aluminum.**—No change is reported, and quotations are firm at 68c per pound.

#### Machine Tools and Supplies

The requirements of the munition makers, in regard to machine tools, have reached a stage where the demand is only for individual tools to supplement their present equipment. Tool builders are, however kept fairly busy, but delivery is much better; in fact, almost normal. The quantity of re-sale machinery is constantly increasing, owing to some of the plants having completed their orders on the smaller shells. The demand for small tools and machine supplies continues very heavy.

#### Scrap

The market has taken on increased activity, and the demand is good; dealers reporting fair business. Old and scrap copper has been advanced  $\frac{1}{4}$ c per pound, quotations running from 16 $\frac{3}{4}$ c for light and 19 $\frac{1}{4}$ c for heavy. An advance of  $\frac{1}{4}$ c has been placed on machine turnings and compositions, the former being quoted at 12 $\frac{3}{4}$ c and the latter at 14 $\frac{3}{4}$ c. Brass clippings and turnings show a similar increase, being 13 $\frac{3}{4}$ c and 12 $\frac{1}{4}$ c respectively. Scrap zinc at 7 $\frac{3}{4}$ c shows an advance of  $\frac{1}{4}$ c

per pound. Aluminum is now 35c, an advance of 1c per pound.

**Toronto, Ont., Sept. 5.**—The situation in manufacturing circles continues satisfactory and the outlook is favorable as regards getting business, although the shortage of labor and probably further increase in cost of raw materials are causing considerable anxiety among manufacturers. While production is being curtailed on this account, business continues to expand, which is proved by the marked increase in railway earnings, trade returns, bank clearings, etc. The increases shown each month reveal the substantial and progressive improvement in the industrial situation. The Customs returns for August, recently issued, show an increase of \$3,610,000, the total revenue for the month being \$11,941,000. The returns each month have shown increases, which are indicative of the phenomenal expansion in trade.

The threatened railway strike in the United States, which would have had

#### CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion \$100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

far-reaching effects, even in Canada, has fortunately been averted. Embargoes had already been placed on shipments to United States points, but were withdrawn a few hours after the notice had been issued. The local freight yards are already sufficiently congested without any further troubles. The first week of the Canadian National Exhibition has been a great success, being favored with exceptionally fine weather. The exhibits in the Machinery Hall are well up to previous years, while the exhibit of munitions in the Educational Building is a new feature which has proved both interesting and instructive, particularly to the general public.

#### Steel

The steel trade continues extremely active, with an increase in production, now that the weather has become cooler. The demand for steel is, and will continue to be for many months, so great that the steel mills are assured of capacity business for some time to come. The steel companies are devoting themselves principally to the manufacture of steel for munitions and other war ma-

terial, with the result that domestic trade has suffered and deliveries consequently have fallen behind. On this account some consumers have had to defer buying, and work is being held up pending a return to more normal conditions. Several buildings have been delayed, and some held up indefinitely owing to the difficulty of getting steel. There are no price changes to note this week, but the market continues very firm, and further advances in steel products may be looked for. Boiler tubes and plates are firm at the advance announced last week, and deliveries are as backward as ever, owing to the sold-up condition of the mills. The wrought iron pipe situation is unchanged with quotations very firm on both black and galvanized pipe. The high-speed tool steel situation is easier owing to the increase in available supplies of tungsten. The demand for tool steel continues heavy, supplies still being difficult to obtain, although prices have an easier tendency. There has been no further change in prices of steel bars, and present quotations will probably be maintained for some time.

There has been no change during the week in the sheet situation. With the high price and scarcity of sheet bars, prices of sheets have been well maintained, and no decline may be expected for some considerable time. The output of the sheet mills has improved with the cooler weather, but deliveries are still backward. The galvanized sheet situation is more settled following the improved tone in the spelter market, but with the continued high price of black sheets, acids, etc., and also increase in wages, lower prices on galvanized sheets do not appear at all likely in the meantime.

In the United States, production in August was about equal to July, in spite of the hot weather, etc. New business, however, was larger, and at the end of the month will probably show an increase in unfilled orders. The steel market has been active during the past week with the buying of large amounts of rails, car plates and general steel products. Export business continues large, while the domestic demand is also heavier. Prices on all steel products are very firm, with no changes of importance to note.

#### Pig Iron

There is nothing of particular importance to note in the pig iron market this week, and quotations are unchanged. The heavy demand for steel-making pig iron continues, and the consumption this year will break all previous records. An indication of the heavy consumption of pig iron in the United States and Canada is shown in the iron ore shipments on the Great Lakes, which for August created a record. In August there were loaded 9,850,140 tons, which was nearly

two million tons greater than for the corresponding month last year.

### Machine Tools

The machine tool market continues active, the situation being practically the same as during the past few weeks. The demand is still confined almost entirely to tools for munition plants, although there is fair inquiry for toolmakers' equipment. Reference has previously been made to the fact that American machine tool houses have to pay a war tax on profits arising out of business transacted in Great Britain. Large concerns, however, say that this will not cause them to close their branch offices in Great Britain, as they will be useful in looking after business previously booked as well as that placed in the future.

### Supplies

The increase in cost of raw materials has resulted in a tendency to higher prices on practically all steel and brass goods, some lines having already been affected. Shurley & Dietrich hand saws now carry a discount of 15 per cent. Those saws, which were formerly 25 per cent., are now 13 per cent., while lines that used to be 30 per cent., now carry a discount of 21½ per cent.; canvas belting has advanced, the new discount being 50 and 10 per cent. Carpenters' chalk has advanced, due to the difficulty of getting chalk from England, and also the high cost of dyes for the colored chalks. Turpentine is unchanged, but linseed oil has declined, and is now quoted at 86c for raw and 89c for boiled oil per gallon.

### Metals

Quotations on most metals have been well maintained, particularly copper, which, although unchanged, is strong, with an upward tendency. The demand continues good for metals for munitions, while ordinary business during August was above normal.

**Copper.**—The market continues strong at unchanged prices, which are still nominal. Domestic buying is improving and the export business continues heavy, but it is reported that the enormous sales predicted for export recently have not materialized as yet. However, without the large buying for the Allies, which had been expected, practically all available supplies for the remainder of the year have been disposed of. Local quotations are firm at 30c per pound.

**Tin.**—The market is unsettled and lower in London, but unchanged locally. The local market is quiet, tin being quoted at 44c per pound.

**Spelter.**—The demand has fallen off, and the market is quieter, with quotations nominal. Local quotations are unchanged at 14c per pound.

**Lead.**—The market is very dull, and easier. The Trust price of 6.50c New York has been maintained, but the in-

dependents' quotations are a shade easier at 6.67½c New York. Local quotations are unchanged at 8½c per pound.

**Antimony.**—There has been practically no demand for antimony during the week, and the market is stagnant. Quotations, however, are unchanged at 17c per pound.

**Aluminum.**—The situation in this metal is unchanged. Local quotations, 68c per pound.

## CANADA AND BRITISH WEST INDIES

E. L. PEASE, vice-president and managing director of the Royal Bank of Canada, in a statement to The Financial Post regarding the benefits of closer relations between Canada and the British West Indies, says in part:

"Annexation or some other form of political union would undoubtedly prove very advantageous to both countries. The entire business element and native population of the British West Indies being strongly pro-British, favors the idea. Jamaica did not come into the recent tariff agreement with Canada, owing to fear of the loss of her banana trade with the United States; but if the movement now on foot in Great Britain to increase the production of sugar within the Empire by means of a preference is achieved, little fear of opposition on the part of the West Indies to annexation need be entertained. Owing to the geographical situation, government from this side of the Atlantic would be more practical than from England.

### W. I. Trade Neglected

"The trade of the West Indies has been almost criminally neglected in the past. The sugar industry, which at one time was the main industry, nearly suffered extinction, owing to the impossibility of competing with the bounty-fed production of Continental Europe and the preference given to Cuba by the United States. The antiquated mills in use in the West Indies accentuated this condition. Canada, which absorbs their entire production, which was about 200,000 tons last year, revived the industry somewhat by granting a preference two or three years ago. Possessing, however, the elements that would tend to cheap production—namely, a rich soil and cheap labor, it is estimated that the British West Indies are capable of producing 3,000,000 tons per annum, enough to supply the requirements of the United Kingdom. The phenomenal prosperity of Cuba is due to the preferential sugar tariff of the United States. In 1901 Cuba produced about 500,000 tons of sugar; last year she produced 3,000,000 tons. Porto Rico, whose sugars enter

free into the United States, produced less than 100,000 tons in 1901, and over 400,000 tons last year, double the production of the entire British West Indies. The volume of trade of this little island is also in excess of the entire trade of the British West Indies.

### Mutual Benefit

"Much as the West Indies would benefit commercially and politically by union with Canada, the advantages would not all lie with that country. The more general interchange of trade that would result would be of incalculable benefit to Canada. Last year our tropical imports exceeded \$30,000,000, of which only \$6,000,000 came from the West Indies. Canada's exports to the West Indies are steadily increasing, and increased prosperity within the West Indies would naturally greatly increase the demand for our exports. At present the exports of fish aggregate £500,000, and our flour has, owing to the preferential tariff largely supplanted American flour."

## LACHINE CANAL AUGUST TRAFFIC

WHILE there is a decrease in the amount of wheat, and consequently in the total amount of grain, to come down the Lachine Canal in the past month, when compared with the corresponding month of last year, still there are substantial increases in the amount of produce, coal, number of passengers, and in the number of ships and the total tonnage.

During last month only 1,128,406 bushels of wheat came down the canal, while for the same month last year there were 3,107,618 bushels, a difference of 1,978,212 bushels. This however is largely compensated for by the large increases in other grains. There was an increase of 1,706,116 bushels of oats, 366,000 of corn, 199,740 of barley and 81,000 of rye. The decrease in the amount of all grains for the month is 318,678 bushels, and this added to the decreases for the other months of the present season, make a total decrease of 8,674,761 bushels, compared with the amount for last year.

The decrease it is said, is in part due to the fact that many of the ships in former years were grain have been commandeered by the Government and are at present transporting other commodities; as a result, a large portion of the grain that came down the St. Lawrence for exportation now finds its way to American ports.

No flour was brought down during the past month, but the same is true of August last year. There were 39,873 boxes of cheese, an increase of 7,700

over last year; 1,292 barrels of apples, an increase of 924; 1,040 boxes of butter, and increase of 179; and 1,460 cases of eggs, a decrease of 469 cases. There was also a substantial increase in the amount of coal to pass down the canal. In the past month the total of 277,667 tons, compared with 158,710 for August, 1915.

There were 1,217 vessel trips made through the canal in the last month, which is 101 more than during the same month last year. The increase in tonnage is even more marked last month, having been 687,037, while a year ago it was 589,317. The total number of passengers to come down the canal, or down the Rapids, in the past month was 27,263, which is an increase of 6,910. In the total cargo there is also an increase, the figures for last month being 538,988, compared with 470,931 for August last year. This year was an increase in the number of ships to pass through the canal light the figure being August, 1916, 406; August, 1915, 369.

### WILL ENLARGE HYDRO SYSTEM

EXTENSIONS and improvements involving an expenditure of well over a million and a quarter dollars are being undertaken by the Provincial Hydro-Electric Commission to meet the ever-increasing demand for Hydro power. The announcement was made recently by Sir Adam Beck and preliminary work is already under way.

#### Double Transmission Line

The chief item of new work is the doubling of plant and equipment from Dundas to Toronto. Largely to meet the

needs of Toronto the Commission has decided to go ahead with the construction of a new double transmission line between Toronto and Dundas, and practically to duplicate the Toronto station—the expenditure being estimated at something over a million dollars. At Dundas the Commission is also practically duplicating the big inter-switching station there at a cost of approximately \$250,000. At Niagara Falls new switches and other equipment to handle the 50,000 additional horse-power being secured from the Canadian Niagara Power Co. will be installed.

The first instalment of power received from the Canadian Niagara Co. has now been added to by a second 12,500 h.p., which was taken over within the past week. For the new double line out of Toronto the plans and specifications have been completed and the right of way is being acquired. The new right of way, it is stated, will include sufficient room for the construction of a radial railway between Toronto and Dundas when in the future it is decided to go ahead with it.

#### Will Link Up Plants

The attention being given the Niagara district does not leave other districts neglected. The Commission undertaking at once the building of two connecting lines in the Owen Sound-Collingwood district to pool the power resources of the four development plants now operated by the Commission there—the Big Chute, Eugenia Falls, Swift Rapids and Wasdell Falls plants.

The Commission is building thirty-five miles of transmission line from Collingwood to tap the Eugenia Falls line to Owen Sound, thus linking up the Falls development with the Big Chute. A six-

mile line from Wasdell Falls meeting the Orillia line from the Big Chute completes the circuit. Eugenia Falls has a power surplus of 4,000 h.p., while Wasdell Falls has 1,000 h.p. more than is being used in that district. This surplus gives the Commission almost immediately the added supply needed to serve the municipalities hitherto depending upon the Big Chute, or a total supply from all four developments of 15,000 h.p. The Commission estimates that with the increased development possible at the Big Chute and the developments yet to be made on the Saugeen and Severn Rivers there is an ultimate development in the district of 25,000 h.p. When this is all in use at some future date the northern municipalities can be linked up with the Niagara system by a six-mile line at Forest.

The tremendous increase in consumption is heavy, due to the demand from all over the system. New municipalities are being added, and those already in are increasing consumption steadily. A part of the increase is due to the manufacture of munitions.

### DOMINION BRIDGE CO. SUBSIDIARIES

The Dominion Copper Products Co., one of the two successful subsidiaries organized by the Dominion Bridge Co., since manufacture of munitions was started in Canada, has secured authority to increase its capital from \$400,000 to \$1,000,000.

Both the Montreal Ammunition Co. and the Dominion Copper Products, organized through the Bridge company to manufacture parts required in shell making, were given a capitalization little more than nominal to the volume of

## Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

#### BRAZIL

Bahia, British Consul.  
Rio de Janeiro, British Consul General.

#### CHILE

Valparaiso, British Consul General.

#### COLOMBIA

Bogota, British Consul General.

#### ECUADOR

Quito, British Consul General.

#### EGYPT

Alexandria, British Consul General.

#### FRANCE

Havre, British Consul General.  
Marseilles, British Consul General.

#### INDIA

Calcutta, Director General of Commercial Intelligence.

#### ITALY

Genoa, British Consul General.  
Milan, British Consul.

#### MEXICO

Mexico, British Consul General.

#### NETHERLANDS

Amsterdam, British Consul.

#### PANAMA

Colon, British Consul.  
Panama, British Vice-Consul.

#### PERU

Lima, British Vice-Consul.

#### PORTUGAL

Lisbon, British Consul.

#### RUSSIA

Moscow, British Consul General.  
Petrograd, British Consul.  
Vladivostok, British Consul.  
Odessa, British Consul General.

#### SPAIN

Barcelona, British Consul General.  
Madrid, British Consul.

#### SWEDEN

Stockholm, British Consul.

#### SWITZERLAND

Geneva, British Consul.

#### URUGUAY

Monte Video, British Vice-Consul.

#### VENEZUELA

Caracas, British Vice-Consul.

business which developed for both concerns. The Ammunition Company started off with a capital of \$300,000, but the actual amount of money required to get that enterprise under way is said to have been many times that amount. The Bridge Company, with its strong cash position, was able to finance the advances required in the early days of organization. Latterly the company has built up a remarkably strong cash position of its own.

The Copper Products Co., which was organized some months later, or about a year ago, was also given a low capitalization, but the present increase authorized suggests that it is proposed to make the capitalization approximate more closely to the expenditure that may be made in connection with enlargement of original plans.

## MARINE INSURANCE

By E. V. Pannell.

FROM the earliest times cargo-owners and shipowners have recognized the necessity of safeguarding their property against the risks of the sea. In the early days of the Christian Era, when the Phoenicians and Tyrians traded with Spain, Gaul, and Britain, their frail ships were sometimes overtaken by tempests, which could only be ridden out safely by lightening the craft; it, therefore, became customary under extreme stress of weather to jettison a portion of the cargo. The loss thus occasioned was shared equitably by the various cargo-owners, and thus the principle of "General Average" was established. The word "Average" signifies "Damage," and of such, present-day marine insurance recognizes two kinds: "General," implying loss, as above described, by jettison, and "Particular," covering damage due to other causes.

### Initiation of Marine Insurance

In the year 1670 a society of ship-owners and master marines, meeting at Lloyd's coffee house in Cornhill, London, formed a marine intelligence department, issuing a shipping bulletin three times a week, which exists to-day under the well-known form of Lloyd's list of British and Foreign Shipping. About 100 years later the same society formulated the marine insurance policy which is now in use all over the world. Many other companies besides Lloyd's underwriters are handling marine insurance, but the form of policy and the warranties are practically universal.

### Insurance Scope

The scope of insurance has been greatly extended, for, although it was the original intention of marine insurance to cover only the risks of the sea which no skill or care could prevent, policies

may now be taken out to cover any conceivable risk. The underwriters have always reserved certain "warranties" or stipulations by which they exclude certain risks. For instance, a clause will be found at the foot of a marine policy stating "Corn, fish, salt, fruit, flour and seed are warranted free from average except general, unless the ship be stranded, sunk, burnt or on fire." Put in other words, this means that the above commodities are excluded from insurance except in the case of jettison or the ship be lost, in which case it is most probable that a total loss could be claimed. The object of the clause is apparent, as the above mentioned articles are peculiarly liable to damage, and hence not a good risk. This is the F.P.A. (free of particular average) clause which normally appears on every policy, but which may by arrangement with the underwriters be over-ridden.

A further warranty states: "Sugar, tobacco, hemp, flax, hides and skins as warranted free from average under five pounds per cent." This was designed to relieve the underwriters from having to settle petty claims for particular average amounting to less than 5 per cent. of the value of the goods insured. A similar clause related to the vessel itself, the limit in this case being 3 per cent. With a large and valuable cargo, 5 per cent. would amount to quite a large sum; it is, therefore, customary for shippers to protect themselves by dividing up the cargo into £100 blocks. By this means damage, which would amount to less than 5 per cent. on the whole cargo, will, if localized, probably reach very much more on the smaller lot, then particular average can be claimed and paid.

Two other warranties which are not mentioned, but are implied in the policy, are "Seaworthiness and Legality." The first covers absence of overloading, proper stowage, efficient manning, absence of cargoes of unusual risk, etc., whilst legality would be affected by the carriage of contraband or the insurance of a foreign vessel against war risks.

### Insurance Comparisons

Comparing marine insurance with fire or theft insurance on land, it will be seen that there are certain distinctions. On land, a policy is a contract of indemnity by which the insurance company undertakes to restore the original condition of the property insured. It can hardly be said that marine insurance is of the same nature because there is no burden on the insured to prove the value of the loss, and in many cases it would be impossible to do so. Further, the issue of P.P.I. (policy proof of interest) policies to some extent lends itself to speculation. Nevertheless good faith is essential to the policy, and misrepresentation or concealment immediately render the

insurance void. If the misrepresentation is accidental, it is customary to return the premiums otherwise they are forfeit. At the time of taking out the policy, all circumstances liable to influence the underwriters must be divulged, default in this regard being equivalent to concealment.

### "Sailing" Clause

Besides the F. P. A. clause and the implied warranties already mentioned there are certain other warranties which are expressed in the policy. One is the warranty to sail on a certain date. To "sail" in this case is to cast off moorings or to weigh anchor and does not necessitate clearing the port. The insurance in this case would cover stranding of the vessel after castings off but before the port was cleared. If, however, the policy contains the words "sail from the port of \_\_\_\_\_," the port must be cleared, otherwise the policy is void. This is an important point in war time as it is possible that the ship might be lost by a mine or infernal machine before clearing her port. The F.C.S. (free of capture, seizure, detention and the consequences thereof) clause is one which practically eliminates war risk and therefore in times like the present is usually over-ridden by being omitted or the words "including war risk," inserted in the body of the policy. Warranties sometimes given to the underwriters with the object of securing better rates are "part value uninsured," and "no iron or ore in excess of registered tonnage is carried."

### Total Loss

In some cases the insurer will take out a T.L.O. (total loss only) policy thus eliminating particular average. Total loss is of two kinds, actual and constructive. The first applies when:—

(a)—The ship or subject matter is completely destroyed.

(b)—The matter is so damaged as to cease to be the subject of the insurance, "cease to exist in specie."

(c)—The assured is irretrievably deprived of the subject matter.

As an example of (b), a cargo of hides shipped from Valparaiso to Bordeaux were so badly damaged during passage as to putrify. It was, therefore put ashore at Rio as it was claimed that at the journey's end they would cease to exist in specie. Total loss was therefore paid.

Constructive total loss applies more often to the ship than to the cargo. It covers the circumstances where the goods are reasonably abandoned, or where the cost of recovery would exceed the value of the goods. In this case the insured hands to the underwriters a notice of abandonment formally surrendering all interest in the goods and claiming total loss. As a formality, the

underwriters usually decline this notice so that same is accompanied with a writ and a formal action is entered for the recovery of T.L. based on the facts at the time of issuing the writ. Upon satisfying the claims the underwriter acquires all the rights of the insured by what is termed subrogation. Such rights may be the result of proceeding already instituted for compensation (in the case of collision), or salvage.

#### Payment of Insurance

When insurance has to be paid, the necessary investigations and apportionments are made, not by the underwriters themselves, but by an entirely independent body of highly specialized professional men, the average adjusters. Their work is frequently very difficult, particularly where general average is paid. It will easily be seen that if ten thousand dollars worth of a fifty thousand-dollar cargo were jettisoned the adjustment of the average payable by each of the separate shippers is no simple matter. In order to avoid detention of cargo it is usual, where a G.A. has been incurred, for the cargo owners to sign

an average bond undertaking to pay their share of the G.A., when it has been computed, and they are called upon. Upon this understanding the cargo is delivered to the consignee. The average bond usually calls for a bank deposit as security. In order to avoid ambiguity as to the laws of general average which vary in different countries, the policy usually specifies that the York-Antwerp rules shall govern both G.A. and salvage. The foreign general average clause over-rides this and stipulates that the laws governing G.A. shall be those of the country of destination.

#### Period of Insurance

Insurance attaches from the time goods are safely loaded until they are safely landed. The policy is sometimes extended to cover between "shipper's and consignee's" warehouses, and this sometimes involves transfer by lighter or railroad. If insured for "voyage," however, the insurance ceases to attach 24 hours after mooring. Goods are generally insured between specified points or for voyage, but ships are usually covered by time policies for six months or one year.

Certain peculiarities attach to a marine insurance policy. For instance, as already noted, the F. P. A. clause states that average will not be paid except the ship is stranded or lost. However, a rider to the policy asserts that "grounding in the Suez Canal, Manchester Ship Canal, River Plate," and certain other locations "shall not be deemed a stranding." This clause is inserted because it is an everyday occurrence for a ship's keel to touch bottom in these channels.

Marine insurance was originally designed to protect shippers from losses due to the perils of the sea, piracy, restraints or rulers and princes, barratry of the master or crew, and jettison. It is, however, extended in modern times to cover any conceivable risk. Certain liabilities must, however, be undertaken by the shipowner and are accepted by the bill of lading. These are: (a) Improper stowage; (b) Negligence of servants; (c) Pilfering.

The shipowner's liability is limited, and the shipper's only really satisfactory indemnification is afforded by a policy of marine insurance.

## CANADIAN COMMERCIAL INTELLIGENCE SERVICE

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

# INDUSTRIAL <sup>A N D</sup> CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

## Engineering

**Chatham, Ont.**—The Gray Dort Motor Co. will build an addition to its plant here.

**Hanover, Ont.**—The Hanover Cement Co. proposes to purchase additional machinery and equipment for its plant.

**St. John, N.B.**—The new plant which is being built for McAvity & Sons is almost completed and will soon be in operation.

**New Westminster, B.C.**—The Western Marine Railway Co., has commenced work on the new shipyards on Poplar Island. The plant will cost about \$80,000.

**Windsor, Ont.**—The Maxwell Motor Car Co. expects to start shortly on the erection of a plant to cost \$60,000. A site was purchased from the city last spring.

**Estevan, Sask.**—The Lignite Briquette & Power Co., propose establishing a brick and tile plant. A plant for making briquettes from lignite is also contemplated.

**St. John, N.B.**—The City Council has decided to proceed with the construction of a power house and laundry of the General Public Hospital at an estimated cost of \$46,000.

**Welland, Ont.**—The Canadian Steel Foundries, Ltd., are building an addition 40 ft. by 100 ft., to the muck bar mill, and will install hydraulic forging presses and gas furnaces.

**Orangeville, Ont.**—The Canadian Clock Co., propose to build a factory, estimated to cost \$30,000, and a by-law will be submitted to authorize a loan of \$15,000 to the company.

**Port Moody, B.C.**—Construction work will be started at once on the erection of a shipbuilding plant for Boyds, Ltd., of Port Moody, to include engineering and wood-working plants, foundry etc.

**Sherbrooke, Que.**—The Iron & Metal Supply Co., Montreal, propose to erect a factory, at an approximate cost of \$15,000. A by-law will be submitted to the ratepayers to sanction certain concessions.

**Brantford, Ont.**—The contractors have commenced to break ground for the erection of the plant of the Dominion

Steel Products Co. The main building, including the office, will be 370 feet by 90 feet. The company has a capital of \$500,000.

**Fredericton, N.B.**—A new pumping station is to be erected at the Experimental Farm to take the place of the station destroyed by fire in March, 1915. The new building is to be two stories high and will cost about \$3,000. William Richards has been awarded the contract for the concrete work. J. A. Grisdale, of Ottawa, is Director of Experimental Farms.

**Ottawa, Ont.**—The contract for the new Dominion Arsenal at Lindsay, Ont., has been awarded to the Westinghouse-Church-Kerr Co., of New York and Montreal. The total cost of the buildings, equipment and plant is not available at the present moment. The estimated cost, however, of the buildings and certain parts of the plant closely associated therewith will be approximately \$675,000. The work is being done through this company upon the same basis on which they carry on all their undertakings. The materials and plant are purchased on the tender basis, the contracts going to the lowest tenderer, all of which are submitted for the approval of the proper officials of the Government. The company are allowed a percentage on the total value of the work, the rate varying in accordance with the amount of engineering services employed.

**Elmwood, Ont.**—The Village Council are considering installing a hydro-electric system.

**Dundas, Ont.**—The Hydro-Electric Commission propose duplicating the equipment at the distributing station here.

**Lethbridge, Alta.**—On September 15, the ratepayers will vote on a by-law to provide further extensions to the electric light system.

**E. P. Coleman**, general manager of the Dominion Power & Transmission Co., of Hamilton, Ont., has been elected president of the Canadian Electric Railway Association.

**Collingwood, Ont.**—The Hydro-Electric transmission line to Eugenia Falls is already in course of construction. The

line will be 35 miles in length and will cost at least \$4,000 per mile.

**Hanover, Ont.**—The Light Commission is considering the extension of the existing lighting plant, or, as an alternative, the construction of a new system. Estimates will be got immediately. Chairman, Dr. Mearns.

**Brantford, Ont.**—The Hydro-Electric Commission will install interswitching apparatus here and also at the Woodstock station. These interswitching stations will break the lines between Dundas and London into three sections. They will eliminate breaks in the service such as have occurred recently.

**New Westminster, B.C.**—By changing from arc lights to the new nitrogen lamps, the cost of the arc lighting system of the city can be reduced from \$12,914 to \$4,673, a substantial saving of \$8,241. This was the report made to the City Council in committee by City Electrician Digby. The change was authorized.

## General Industrial

**St. Jerome, Que.**—The Regent Spinners, Ltd., will build a mill here.

**Renfrew, Ont.**—The Renfrew Textile Co., will build an extension to their factory.

**Wingham, Ont.**—The Wingham Salt Works will shortly install machinery at their new brine well.

**London, Ont.**—The Hunt Milling Co. are contemplating the erection of an addition to their flour mill here, to cost \$50,000.

**Toronto, Ont.**—The Corrugated Paper Co., has let a contract for the erection of a brick and steel addition to its plant to cost \$12,000.

**Medicine Hat, Alta.**—It is expected that the new mill being constructed by the Lake of the Woods Milling Co., will be completed this year.

**London, Ont.**—The Canadian Cereal & Flour Mills Co. propose to erect an addition to their premises on Talbot street, at an estimated cost of \$10,000.

**St. Jerome, Que.**—The Canadian Consolidated Rubber Co., will build a large addition to its plant at St. Jerome, Que., and has awarded the contract to Gray & Dunn, Montreal.

## Electrical

## Boring Economy

Two great factors in economic boring operations are the Bridgeford Boring Lathe and the Davis Boring Heads. Combining the massive strength of this Bridgeford Lathe and the tough, superior quality of a specially constructed Boring Head and you have an ideal combination that will save you at least 25 per cent. to 50 per cent. on your Boring operations. The lathe is a machine of ideal proportionate strength, the stresses have been scientifically calculated, the vital points strengthened, resulting in a smooth-running, perfectly balanced unit that ensures efficiency, economy, speed and superior production.

### Bridgeford 9.2" Boring Lathe

The lathe is of the heavy duty, low swing type, having a specially designed carriage with auxiliary hand feed for internal profile. Carries a 6 inch steel bar with male taper, allowing for light designs of cutter heads; 3 automobile style speed changes, all running in oil bath. A chip tray is attached and is used in conjunction with stationary lubricant tank. Regular equipment comprises everything except chuck, steady rest and cutter.

### Davis Boring Heads

The boring heads are a new construction. Having benefited by the experiences of the "pioneering days" this type of head has been constructed, making a direct cut in the cost of boring operations of 25 per cent. to 50 per cent. Being made of that superior quality high speed steel you will have boring heads that will last, that will prove to you their saving power.

A 25% to 50% saving on boring operations will be welcomed by shell manufacturers. Illustrated here are four boring heads: Rough bore, straight diameter; finish bore, straight diameter; rough bore, inside radius; finish bore, inside radius. These heads may be adapted to any lathe and will give you economical, speedy and efficient service.

*Write us for particulars.*

Rough Bore, Straight Diameter

Finish Bore, Inside Radius

**The A. R. Williams Machinery Co.**  
64-66 Front St. W. - Toronto, Ont., Canada

*If any advertisement interests you, tear it out now and place with letters to be answered.*

**St. Thomas, Ont.**—The Neal Bread Co., of London, Ont., will in the near future erect a modern bakery in this city. The location or size of the building was not stated.

**London, Ont.**—The J. R. Shuttleworth Co., hat manufacturers, are preparing plans for an addition to their factory on Dundas street. The building will be of brick construction and will cost about \$10,000.

**London, Ont.**—The H. S. Hall Co., of Jersey City, have opened factory premises here and will manufacture lisle and chamoisette gloves. The company propose building a factory in the spring at a cost of \$25,000, to weave the fabric required in the manufacture of the gloves. Chas. Phillips, of Toronto, represents the company.

**Brantford, Ont.**—Two Hamilton men will have joint management of the Brantford Carriage Co., which was recently amalgamated with the Baynes Carriage Co., of Hamilton. The managers will be Messrs. McTaggart and Jex, both of the Baynes Co. The stock in trade of the Baynes Co. is now being transferred to this city.

**Niagara Falls, Ont.**—A by-law will be submitted to the ratepayers on Sept 18, to grant a remission of taxes for ten years and necessary electric power at \$10 per h.p., to the Perfection Tire & Motor Co., of Madison, Wis., who propose establishing a factory here. A site covering 15 acres has been secured. Richard T. Evans, of Madison, Wis., is vice-president of the company.

**London, Ont.**—The Middlesex Mills, Ltd., which has a capital of \$250,000, has purchased a factory building here and will manufacture cotton, linen, silk and woollen goods. The building has over 25,000 square feet of floor space. The company will handle everything connected with the manufacture of the product except the spinning of the yarn. They have their own dye plant and will make their own chemicals for bleaching purposes.

**Peterboro, Ont.**—The contract for the erection of the Lambton Flax Co. plant has been let to the J. J. Kerr Co., of this town, for \$15,000. Work will be begun at once, and some of the buildings and the retting tanks are to be completed this fall, the balance next spring. The buildings will be of the most modern type for flax mill purposes and are intended to serve as a Government model for flax factories.

## Municipal

**Edmonton, Alta.**—The City Council propose purchasing additional fire fighting apparatus.

**Merrickville, Ont.**—A by-law to grant a loan of \$30,000 to the Rideau Power Co., was defeated by a majority of 85 to 6.

**New Glasgow, N.S.**—The Town Council contemplate extending the waterworks system. E. S. Fraser is town engineer.

**St. Thomas, Ont.**—The City Council are considering the construction of a sewage disposal system. M. Ferguson, City engineer.

**Dunnville, Ont.**—A by-law will be noted on by the ratepayers on Sept. 25 to raise \$53,000 for installation of a hydro-electric plant.

**Bassano, Alta.**—A by-law will be voted on to raise \$7,000 for the purchase of the electric light and power plant of the Alberta Electric Co.

**New Glasgow, N.S.**—The Town Council propose extending the waterworks system at a cost of \$100,000. E. S. Fraser of New Glasgow is preparing plans.

**North Bay, Ont.**—On Sept. 18, a by-law will be voted on to authorize a \$15,000 guarantee of bonds of the North Bay Hat Mfg. Co., with other concessions.

**Aurora, Ont.**—The Town Council have engaged James, Loudon & Hertzberg, consulting engineers of Toronto, to prepare plans for a sewerage disposal system.

**Aylmer, Que.**—The lowest tender recently received for the proposed water filtration plant was submitted by the Norwood Engineering Co., of Cowansville, Que., at \$33,000.

**Lethbridge, Alta.**—A by-law will be submitted to the ratepayers on Sept. 15 to raise \$9,375.66 for extension of electric light system; \$1,000 for extension of ash flue at electric power house; \$6,700 for extending electrical system.

**Winnipeg, Man.**—A tender for the entire completion of the capital building was submitted by J. McDiarmid & Co., for \$3,128,018. The lowest tender for the steel work in the dome was submitted by the Manitoba Bridge & Iron Works at \$169,960 and for the plumbing, heating and ventilating Green & Litsten at \$203,981.

**St. Mary's, Ont.**—At a special meeting of the Council on Aug. 28, a resolution was passed urging the Water and Light Board to install the gasoline pumping plant recommended by the inspector of the Underwriters' Association on his visit here last March. The sum of \$4,000 has been voted for the purpose. It is proposed to drill new

wells, making the new plant entirely independent.

## Wood-Working

**Harriston, Ont.**—The casket factory here was destroyed by fire on Aug. 30. The loss is heavy.

**Windsor, Ont.**—The Windsor Lumber Co. are building a large addition to their mill on Cameron Ave.

**New Westminster, B.C.**—The Dominion Cedar & Shingle Co. are clearing the site for their new shingle mill next the Lulu Island bridge on water frontage leased from the city.

**New Westminster, B.C.**—The Marsh Hutton Powers Co. propose to build a shingle mill on Lulu Island, and have leased a site from the city. Approximate cost, \$30,000.

**New Westminster, B.C.**—Fire, on Aug. 24, completely destroyed the shingle mill and boiler room of the Brunette Sawmills Co., in Sapperton, causing damage estimated at \$20,000, covered by insurance. It is expected that the company will proceed at once to rebuild the shingle mill.

## Railways—Bridges

**Victoria, B.C.**—Agreements have been concluded whereby the construction of the proposed Johnson street bridge will be proceeded with.

**St. John, N.B.**—The C. P. R. are reclaiming a large area on the western side of the harbor, to be utilized as a freight yard, with accommodation for 1,800 cars. A 200,000-gallon water tank is also being erected by the railway.

**Montreal, Que.**—The Montreal and Southern Counties Railway intends to construct a number of new terminals along the route between this city and Granby for the accommodation of the increasing business that is now offering.

## Tenders

**Ottawa, Ont.**—Tenders will be received up to Friday, September 8, for the following material: One portable gasoline-driven air-compressor, 100 cubic feet capacity; four pneumatic caulking hammers; two 5-ton chain blocks. Specifications may be obtained on application to A. F. Macallum, Commissioner of Works.

**Ottawa, Ont.**—Tenders will be received until September 29, for the construction of an extension to the west breakwater at Port Stanley, Elgin County, Ont. Plans and forms of con-

# Why the Welland Canal Zone?

**ASK THE ENGINEERS OF THE INTERNATIONAL NICKEL CO.**

They spent two months in examining industrial sites from the Atlantic to Lake Huron. Now they are building their big plant covering 25 acres in the Welland Canal Zone. Why?

**Because of abundant cheap power**

**Because of unrivalled rail facilities**

**Because of the advantages of Lake shipping**

The Welland Canal Zone has the strongest combination of Industrial Facilities in Canada. Twenty-five big industries of continental reputation have proved it in the last five years.

## RAILROAD RATES

Rates from Welland to the North-West and Pacific Coast, all rail, are the same as from all other manufacturing points in Eastern Canada lying between the Detroit River and Montreal. These rates are fixed by the Board of Railway Commissioners for Canada.

On account of the close proximity to the border, Welland is in the Buffalo switching group and takes the Buffalo rate from the east and south, and enjoys quick delivery on all raw material imported from the United States.

The fact that all of these roads centre here creates competition, and is the biggest lever the manufacturers have for securing efficient service from the railroads.

The seven railroads are as follows:

Grand Trunk — Michigan  
Central — Toronto, Hamilton  
& Buffalo—Canadian Northern  
—Pere Marquette — Canadian  
Pacific—Wabash.

Switches or spurs are constructed on the basis of cost, the manufacturing firm paying the cost price and the railroads refunding a fixed sum for every car switched over the spur until the full amount is rebated. This rule prevails throughout the entire Dominion of Canada, and no one district has any advantage in this matter.

*The WELLAND WAY*

**THE SHIP CANAL THAT  
WILL CARRY MORE  
VESSELS & MORE  
TONNAGE THAN  
PANAMA**

## POWER RATES

Welland is the industrial hub of the Niagara Peninsula, where an unlimited amount of electric power is available and sold at competitive prices, owing to the numerous power companies represented there.

Every factory in Welland is driven by electric power supplied by the Ontario Power Company, of Niagara Falls, which is about twelve miles east of Welland, or from the Dominion Power Company of DeCew Falls, which is about twelve miles north of Welland. The fact that we have competitive companies operating in this district gives us competitive prices on power.

## LAKE SHIPPING

Welland is situated on the Welland Canal, the great Marine highway, between tide water and the Canadian North-west, with daily freight service both ways.

The canal carries boats of fourteen-foot draft, but work has now begun on canal enlargement to the amount of fifty million dollars to provide for twenty-five foot draft.

In these days of keen competition, water transportation has become an absolute necessity to manufacturers, and Welland holds the distinct position of being the only municipality in the entire Dominion of Canada, owning and operating its own municipal wharf, accessible by all shippers and steamboat lines alike, without charges of any kind.

Welland is a port of entry for all upper lake lines of steamers giving low rates and quick dispatch, the advantages of which are enormous.

**Send for Booklet that tells the story of Welland from the Manufacturer's standpoint.**

**Louis Blake Duff,**  
Industrial Commissioner, WELLAND, CANADA

*If any advertisement interests you, tear it out now and place with letters to be answered.*

tract can be seen, and specification and forms of tender obtained at the Department of Public Works, Ottawa, at the offices of the District Engineers at Windsor, Ont., and Equity Building, Toronto, Ont., also on application to the Postmaster at Port Stanley, Ont.

**Ottawa, Ont.**—Tenders addressed to J. W. Pugsley, Secretary Department of Railways and Canals, Ottawa, Ont., will be received up to September 18, for the construction of foundations for 500,000 bushel storage capacity grain elevator, working house and track shed at St. John, N.B. Plans, specifications and blank form of contract may be seen at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa; at the office of the Chief Engineer, Moncton, N.B.; at the office of the Terminal Agent, St. John, N.B., and at the office of the John S. Metcalfe Co., Ltd., Engineers, Montreal, P.Q.

**Ottawa, Ont.**—Tenders will be received up to October 2, for the under-mentioned metal supplies for delivery to H.M.C. Dockyards at Halifax, N.S., and Esquimalt, B.C.: Items 1, steel angles, bars, sheets and plates; 2, iron bars, fire bar; 3, brass bars and sheets; 4, copper sheets and bars; 5, solder, tin, and alloys; 6, tubes, brass and copper. Forms of tender and full information may be obtained by application to the Department at Ottawa, or to the Naval Store Officers, at H.M.C. Dockyard, Halifax, N.S., and Esquimalt, B.C. In making application for forms, the particular item or items for which forms are required should be clearly stated.

**Chesley, Ont.**—Tenders will be received until September 11, for the following material taken from the Chesley Electric Light Co.'s plant, which was bought by the town and rebuilt by the Hydro Commission: 1,661 lbs. .03 heavy plain copper wire, unburned; 4,192 lbs. scrap copper wire, large sizes; 1 120-kw. 125-cycle, 2,300-volt, single-phase C. G. E. alternator; 1 3-kw., 125-cycle exciter; 1 marble switchboard for generator; 1 100-light arc generator; 1 30-light Reliance arc generator; 1 25-light Reliance arc generator; 14 133-cycle transformers; about 40 arc lamps. For further information apply H. S. Sanderson, Clerk.

## Contracts Awarded

**Port Arthur, Ont.**—The C. N. R. have awarded a contract for the proposed machine shop to J. H. Simmons, of Winnipeg.

**Vancouver, B.C.**—Contracts for the new Portages Theatre have been awarded to Stone & Christie for the masonry and terra cotta work, at \$95,980, and

to Coghlan & Sons for the steel work, at \$35,000. The heating and ventilating contracts have not been let. The entire cost of the building will be about \$300,000. B. M. Priteca, of this city, is the architect.

## Marine

**Ottawa, Ont.**—The Marine Department will notify shipping to suspend traffic above Quebec on September 11, the day on which the middle span of the Quebec bridge is to be floated into place.

**St. John N.B.**—The Norton Griffith Co. are proceeding with harbor development work at East St. John. Three dredges are at work, in addition to crews employed in finishing a breakwater and in excavating for a dry dock.

**Port Arthur, Ont.**—The Western Drydock & Shipbuilding Co., have signed contracts for two more freighters the same size and type as the two at present under construction. The company has also in sight four other freighters of the same design.

**St. John, N.B.**—The Maritime Dredging Co. are proceeding with the reclamation work in connection with new piers on the western side of the harbor. The total fill will be about 475,000 cub. yds., of which 150,000 cub. yds. have already been dumped.

**Breakwater Completed.**—A notice issued by the Marine Department, Ottawa, on Aug. 30, is to the effect that the breakwater at Goderich, Ont., has been completed to its full length of 1,400 feet, and the check water removed so that vessels can use the harbor on a direct course between the two entrance piers.

**Kingston, Ont.**—The steamers Rideau King and Rideau Queen, which have for years plied between Kingston and Ottawa on the Rideau River, have been taken to Belleville, where an effort will be made to sell them. Since the death of Capt. Daniel Noonan more than a year ago they have not been operated.

**Icebreaker Burned.**—The car ferry icebreaker St. Ignace, owned by the Canadian Towing & Wrecking Co., of Port Arthur, was destroyed by fire on August 30, in drydock at Port Arthur, Ont., where she had been recently taken for repairs. The St. Ignace was a 600-ton vessel, built in 1888. The loss represents about \$50,000.

**C.G.S. "Burleigh"**—The schooner Burleigh will not be sold. She is a trim little vessel and in view of the shortage of tonnage on the Atlantic, it has been urged by maritime interests in

Halifax that the Naval Service Department should sell her. The Department agreed, and a number of bids were received. None of them corresponded with the value of the ship, however, and the tenders have been notified that there will be no sale.

**Quebec, Que.**—Messrs. J. S. Thom, M. J. Hackett and W. J. Hackett, hitherto joint owners of the Quebec Transportation & Forwarding Co., have sold their interests over the entire fleet of tugs and barges of the company to the Canada Shipping Co., of Montreal. The fleet consists of the sea-going tug Margaret, the A. H. Hackett, the J. H. Hackett, and Florence, as well as the barges Zapotic, Gladys, Hackett, Katie Hackett, Frank D. Ewen, and A. D. It is understood that the selling price was \$150,000.

**Windsor, Ont.**—United States engineers will not remove the wreck of the steamer Topeka, sunk abreast of the Mullen's coal dock, Sandwich, a week ago. The wreck lies in 30 feet of water on the Canadian side, and must be removed by the Canadian Government. Vessels navigating the river may pass on either side of the hull, but the wreck is a menace to navigation. The owners have not decided what they will do with the steamer, but should they abandon her, her cargo of coal would well repay wreckers for removing the obstruction.

**Vancouver, B.C.**—The C. P. R. announced recently that it had let a contract to W. D. Grant, of Vancouver, for the carrying out of a comprehensive dredging scheme on the waterfront between sheds 3 and 7. The contract will include the berth in front of the depot shed and the berths immediately east of that part now used by the Pacific Coast Steamship Co.'s steamers and others. The intention is to have a depth of water of not less than 33 feet, and it is very probable that when this work has been finished even bigger steamers than those at present running here will be employed in the service. Orders have been given to have the dredging work carried out with every expedition, and it is expected that a start will be made next week. The contract will entail an outlay of some \$200,000.

**British Masters and Mates.**—A new policy with regard to the admission of mates on British ships has been adopted by the British Board of Trade, according to a notification which has reached the Marine Department, Ottawa. Where formerly any candidate was admitted to the examination for masters and mates certificates and was qualified to take charge of ships of British register if successful, a new rule has been made. From now till the war is over every applicant for a certificate must be a

# 3 BIG REASONS WHY YOU NEED

## PURO

(MADE IN CANADA)

1. Puro Sanitary Drinking Fountains will give you a better water supply cheaper.
2. Puro will cut your water bills 15% to 35%.
3. PURO will safeguard the health of your employees and raise the standard of efficiency.

Are not these reasons enough? Then why hesitate longer?

PURO equipment is not expensive—the first cost is *low* and the up-keep *nothing*. Easily attached; positively fool-proof. Let us make you a special proposition for a try-out in one of your departments. Write us now—to-day—giving us the number of men; an inquiry will cost you nothing.

British subject, and at the time of his birth each parent must have also been a British subject. It is understood, however, that the Canadian authorities will not adopt the same regulations, but will follow the same practice as formerly, admitting only British subjects to the examinations.

## Trade Gossip

**The Wilt Twist Drill Co.**, of Walkerville, Ont., are moving into their new factory shortly. The buildings are of concrete and steel construction and are equipped with the most modern machinery, enabling the company to largely increase their output.

**Toronto, Ont.**—The two-days' sessions of the Ontario Municipal Association, holding its Eighteenth Annual Convention in Toronto, was opened by the president, A. K. Bunnell, City Treasurer of Brantford, on Aug. 30, in the Council Chamber of the City Hall.

**Large Order for Shirts.**—An order for 500,000 shirts, received from the Italian Government, has been awarded by the Department of Trade and Commerce to the Knit Goods Association, of Hamilton. This is one of a number of orders for shirts and blankets received from the French and Italian Governments.

**Ottawa, Ont.**—The Government has refused to accept any of the tenders for the construction of the station buildings in connection with the new Intercolonial terminals at Halifax. The prices quoted were too high, apparently owing to the high cost of materials and labor.

**The Canadian Hoskins Co.**, of Walkerville, Ont., are moving in October to the premises at present occupied by the Wilt Twist Drill Co. The most complete and up-to-date equipment will be installed and will give this growing concern more adequate room for the manufacture of their product, which consists of furnaces and electric pyrometers.

**Britain Gets Whale Oil.**—When the Arctic whalers transferred their trade to the Antarctic, Great Britain obtained control of the whole of that trade by giving out licenses. This carried with it command over an important supply of glycerine, an essential ingredient in the manufacture of the explosive cordite. In return for supplies of coal and other necessities of their business, the licenses were endorsed with the condition that the product of the catch be sold in the United Kingdom. Result: England has received this year 600,000 barrels of whale oil, one-tenth of which was glycerine.

**Record Ore Shipments.**—Another record in iron ore shipments on the Great Lakes was made in August according to figures just made public. There were loaded last month 9,850,140 tons, which was nearly two million tons greater than in August a year ago. For the season to Sept. 1, shipments aggregated 39,215,864 tons, an increase of more than 12,000,000 tons over the same period in 1915, and 7,000,000 tons more than the total movement in 1914. Vesselmen are confident the total shipments for 1916 will reach 60,000,000 tons.

**Customs Receipts.**—A further phenomenal rise in customs receipts indicating the maintenance of this year's remarkable trade increase is shown in the monthly statement issued on August 31, by Hon. J. D. Reid, Minister of Customs. The August revenue from customs reached a total of \$11,941,000 as compared with \$8,330,000, an increase of \$3,610,000. For the five months of the fiscal year, the increase in customs revenue has been \$21,723,000, the receipts having risen from \$36,731,000 in 1915 to \$58,454,000 during the present year.

**Exhibit of Enemy Products.**—Sir George Foster, Minister of Trade and Commerce announced recently that a very complete collection of German and Austrian products sold largely before the war has been made by the British Government and following the British tour the assortment will be brought to Canada. It will be displayed in Toronto and Montreal and probably at other centres. Canadian manufacturers, merchants and consumers alike will find an inspection profitable. Materials, prices, cost estimates, etc., will be made clear.

## Personal

**Hon. F. T. Frost**, president of Frost & Wood Co., Smith's Falls, died recently.

**R. A. Pyne**, superintendent of the C. P. R. shops for the past five years at Winnipeg, has been appointed to the position of superintendent of motive power on the same railway at Montreal.

**T. R. Rieder**, vice-president and general manager of the Canadian Consolidated Rubber Co., has been elected to the Board of Directors of Ames-Holden-McCready, Ltd. His election fills the vacancy left by the recent resignation of A. L. Johnson, who was vice-president and general sales manager of the company. **I. L. Dildine** has been appointed to the position of general sales manager.

E. B. Plewes of E. B. Plewes & Co., manufacturers' agents of Winnipeg, Man., is visiting Eastern Canada and the United States in Connection with his business. Mr. Plewes represents William Hall, Ltd., Alma Works, Sheffield, England, file manufacturers.

Hugh Wilkinson, former mechanical superintendent of the Brockville branch of the Canadian Northern Railway, and for many years previously an employee of the Grand Trunk, died at Brockville, Ont., on August 27. He had long since retired, having reached the age of 28.

H. R. MacMillan, Chief Forester of the Province of British Columbia, who recently returned from a sixteen months' trip to Europe, South Africa, the Antipodes, and India, in the capacity of Special Trade Commissioner for the Dominion Department of Trade and Commerce, with a view of investigating opportunities for the Canadian lumber export trade, has sailed from Victoria, en route to China, Japan, and Russia, to pursue his investigations. He will be absent for about five months. Mr. MacMillan's trip to Great Britain resulted in a number of important war orders for lumber and lumber products being directed to the British Columbia mills, and only the inability to secure adequate ocean transportation facilities prevented this business from assuming very large proportions.

## New Incorporations

The Beacon Match Co. has been incorporated at Toronto to manufacture matches, with head office at Toronto, with a capital of \$75,000. Incorporators: R. M. Melville, F. C. W. Wagner and K. Campbell, all of Toronto.

Martin Aeroplanes, Ltd., has been incorporated at Toronto, with a capital of \$100,000, to manufacture aeroplanes of all kinds at Windsor, Ont. Incorporators: C. S. King, W. L. McGregor and W. R. Bonds, all of Windsor, Ont.

Montreal Machinery & Supplies, Ltd., has been incorporated at Ottawa with a capital of \$50,000, to manufacture and deal in Machinery of all kinds at Montreal. Incorporators are: F. G. Bush, W. R. L. Sharrk and M. J. O'Brien, all of Montreal.

The Oxford Knitting Co. has been incorporated at Ottawa with a capital of \$50,000 to construct and operate cotton and woolen factories. Head office at Woodstock, Ont. Incorporators: William Taylor, Ralph E. Allen and B. S. Crombie, all of Montreal, Que.

The Toronto Furniture Co., has been incorporated at Toronto with a capital of \$500,000 to manufacture furniture of

all kinds at Toronto, Ont. The provisional directors are Joseph M. Bullen, James H. Fraser and Percy Shulman all of Toronto.

**Hanna Bros., Planing Mill, Ltd.**, has been incorporated at Toronto, with a capital of \$75,000, to manufacture sashes, blinds and doors at Fort Erie, Ont. The incorporators are: A. J. Hanna, of Bridgeburg, Fred Hanna and A. R. Ellis, of Fort Erie, Ont.

**The Cushman Motor Works of Canada, Ltd.**, have been incorporated at Ottawa with a capital of \$100,000, to take over the concern of the same name located at Winnipeg, Man., and to carry on business as engineers and machinists, etc. Incorporators: A. E. Donovan, F. K. Hamilton and H. E. Kennedy, all of Winnipeg.

## Catalogues

**The Gray Mfg. & Machine Co.**, Toronto, are distributing to the trade a new bulletin No. 14, dealing with the "Gray" power pumps and water supply systems. The bulletin contains a brief description of the systems and specifications covering the various sizes of pumps and tanks, etc., with price list. The bulletin is illustrated.

**Lathes.**—Lodge & Shipley Machine Tool Co., Cincinnati, Ohio, have issued a complete loose leaf catalogue in which the illustrations and descriptive matter explain the operation of the company's lathes and the various uses to which they may be put. The leaves are arranged so that the several parts of the lathes are illustrated and described first, followed by pages dealing with the completed tool. The lathes listed include engine lathes with cone pulley and selective head arrangements for securing different spindle speeds, a portable lathe and one for heavy forgings. A bulletin giving examples of work done on the various machines is included.

**Pumping Machinery.**—Catalogue No. 29 deals with an interesting line of pumping machinery and air compressors made by the National Steam Pump Co., Upper Sandusky, Ohio. Simplex and duplex pumps for a large variety of purposes, also vacuum pumps, are dealt with, while automatic feed pumps and receivers and air compressors are also included. A general description is given of each type, with special reference to the principal features embodied in their construction. Each type of equipment is illustrated, and tables are included giving the principal dimensions and capacity of each size. The catalogue concludes with a list of parts for several types of pumps, accompanied by diagrams.

## To Makers of Mark Seven 4.5 H.E. Shells

Our "Patent applied for" Special Water-Cooled Die is the only successful Die for the Mark Seven. Shop Licenses and Drawings, \$100.00. Our Nosing Die, Water Jacket, Die and Pin (unfinished) will be supplied at \$40.00 per set. Our form of Die is also applicable to 5 in. and 6 in. Shells.

OUR SPECIAL DIES HAVE THE LONGEST LIFE OF ANY ON THE MARKET. OUR LATEST DIE HAS PRESSED OVER SEVENTEEN THOUSAND SHELLS (17,000).

# The Service

## Capacity and Convenience

of a Hendey Lathe will prove of vital importance to your tool room.

The "Hendey" is accurate in the highest degree and suited for the efficient use of watch tool chucks, stop chucks, relieving attachments, etc.

It has the best spindle construction in its taper journals, with annular bearings and automatic oiling rings, which make for accuracy of alignment.

It has **automatic stop** for carriage working in either direction. Has reverse for carriage, controlled from apron.

Wide range of threads and feeds through mounted gearing, with ability to make gear changes for additional threads and feeds without limit.

**A card will get you full particulars. Why not mail it now?**

## Staff Article

To show the principle of the formulae, the solutions are made on a basis of one second duration of fall.

### Vertical and Horizontal Projection.

The point at which a body will strike when falling freely from a state of rest (action of the air being neglected), will be directly below, and on the same radial line from the earth's centre; but, in the case of projectiles, the striking

of flight is twice that taken for the fall, the height will be from formula (5),

$$H = \frac{1}{2} g T^2 = \frac{32.16 \times 5^2}{2} = 402 \text{ feet.}$$

If, on the other hand, an object is projected in a horizontal direction, the time of flight will be the same as if the object had fallen freely at the moment of projection. If, as shown in Fig. 2, an object is projected from a point A, in a horizontal direction, the height being 402 feet, the elapsed time before the object strikes the ground, will be found to be just 5 seconds, and the range will equal the velocity times the duration of flight in seconds.

Suppose an airship is travelling at a speed of thirty miles

an hour at a height of one mile, and wishes to drop a bomb on a certain position. If travelling directly for the object, at what distance in front, would the shot require to be dropped? The time required for the shot to drop, neglecting the air resistance, would be, from formula (6),

$$T = \sqrt{\frac{2H}{g}} = \sqrt{\frac{2 \times 5280}{32}} = 18.1 \text{ seconds.}$$

in front of the intended object. To overcome the difficulty of judging the distance, it is determined by means of instruments which give the desired angle for that height and speed. Thus, from the formula: Tangent equals side adjacent

$$\frac{5280}{796}, \text{ we get } \frac{5280}{796} = 15076; \text{ and side opposite}$$

the angle (a), Fig. 2. corresponding will be approximately 8 degrees and 34½ seconds.

While the possibility of hitting stationary positions from moving objects, even when previous calculations have been made, are very uncertain, the difficulties of "winging" an air machine from land batteries are considerably greater, as it is practically impossible to make provision for the exact location of a raider, owing to the unlimited working area.

### Angular Projection.

From the foregoing it is evident that field or naval artillery must invariably be fired at an angle with the horizontal to meet the range requirements. With a known muzzle velocity, it is possible to calculate within very close limits, the range of a projectile and also the height of the highest point of its path or trajectory. The muzzle velocity of different ordnance varies according to their size and purpose, often exceeding 2,000 feet per second; but, for convenience of chart making, the velocity here considered is an initial velocity of 500 feet per second.

FIG. 3. TRAJECTORY DIAGRAM AT 30 DEGREES PROJECTION.

point or the range must be determined. To the action of gravity (which is the same in all cases), the additional force necessary to propel the body must be taken into consideration in order to solve the range, etc. If an object is projected in a vertical direction, the action of the body will be exactly similar to that of falling bodies, with the exception that the object starts with an initial velocity, ascends with a constant retarding force to a given

FIG. 4. TRAJECTORY DIAGRAM AT 45 DEGREES PROJECTION.

height, and falls to its original position, attaining a velocity equal to that of projection. For instance, an object is projected vertically, and at the end of 10 seconds returns to the starting point, to what height did it go? As the time

Therefore, as the airship is travelling 30 miles an hour, the shot would require to be dropped

$$\frac{30 \times 5280}{60 \times 60} \times \frac{18.1}{1} = 796 \text{ feet.}$$

FIG. 5. TRAJECTORY DIAGRAM AT 60 DEGREES PROJECTION.

The path of a shell, at a given muzzle velocity, can be graphically constructed, showing the height to which the shell will ascend and the range for that angle. As the only variation in the three charts is that of angular construction,

the following description will refer to all; each one having been drawn to the same scale of time and distance. The action of the first second of projection is shown shaded, with an enlarged view in the upper left hand corner to more clearly illustrate the force of gravity upon the shell travel. The initial or muzzle velocity  $V$ , is represented by the diagonal line, and the horizontal and vertical velocities  $V_1$  and  $V_2$  are represented by the two components AI and II. It is obvious that the value of these two components will vary according to the angle of inclination or projection. Neglecting the resistance of the air, the horizontal value  $V_1$  will remain constant, but the vertical  $V_2$  will be governed by the position of the shell and the time of flight; that is, the path of the projectile will be controlled by the action of gravity working in conjunction with the propelling force.

As shown by the diagram, the shell, instead of continuing in a straight line, will take the path indicated by the heavy curved line; the fall, by gravitation, during the first second being shown by the distance (x), which equals  $\frac{1}{2}gT^2$ . Thus, the path of a projectile can be graphically plotted if the initial velocity and angle of projection are known. From the point A, on the horizontal line AB, erect the diagonal line AC, at the desired angle, and on this line lay off the divisions 1, 2, 3, etc., to represent the velocity in feet per second and to a given scale (in this instance, 500 feet per second for each division). From these points, drop vertical lines cutting the base line as shown, and mark off from the diagonal point, a distance equal to the value found by the formula  $\frac{1}{2}gT^2$ , for that particular second, and measured to the scale of the drawing. In constructing the diagrams, Figs. 4 and 5, it was necessary to divide the diagonal AC as shown, the extension being represented by the short sections DE and FG; the distance (y) being the vertical drop from the preceding section. When the various distances, as found by the formula, have been marked on their respective vertical lines, the trajectory can be traced through the intersections, as shown by the heavy line.

The height H of the highest point S in the trajectory can be found by dividing the product of the square of the velocity  $V$  and the square of the sine of the angle of projection by twice the force of gravity, as shown by formula (10), Fig. 6. The three charts, Figs. 3, 4 and 5, are all drawn to the same scale of time, distance and velocity, the different angles of projection indicating the relative height, range and duration of flight. It will be seen that the longest range is obtained when firing at an elevation of 45 degrees. The shell will, however, attain a higher altitude and

remain longer in flight when fired at an angle exceeding 45 degrees, as shown in Fig. 5. The various formulae, for the solution of bodies projected at an angle are given in Fig. 6, with the following notation:—

$T_1$  equals the total time of flight.

$V$  equals the initial or muzzle velocity.

$R$  equals the range.

$H$  equals the altitude of the highest point of flight.

$U$  equals vertical velocity at end of  $T$  seconds.

$T$  equals the elapsed time from instant of projection.

Solutions to formulae are made on a basis of 500 feet per second initial velocity, and an angle of projection of 45

$$R = \frac{2V^2 \sin. (a) \cos. (a)}{g} = \frac{2 \times 1500^2 \times 5 \times .866}{32.16} = 11.47 \text{ miles.}$$

In the above question, what would be the highest point to which the shell would ascend?

The height point can be found from the formula (10) where

$$H = \frac{V^2 (\sin. a)^2}{2g} = \frac{1500^2 \times 5 \times .5 \times .5}{2 \times 32.16} = 8745 \text{ feet, or 1.66 miles.}$$

A gun is discharged at an angle of 35 degrees with the horizontal, and the shell hits an object at a distance of eight miles, striking 22 seconds after

7	$T_1 = \frac{2V \sin. a}{g} = \frac{2 \times 500 \times .707}{32.16} = 21.9 \text{ Sec.}$
8	$R = V \cos. a \times T_1 = 500 \times .707 \times 22 = 7777 \text{ ft.}$
9	$R = \frac{2V^2 \sin. a \cos. a}{g} = \frac{2 \times 500^2 \times .707^2}{32.16} = 7772 \text{ ft.}$
10	$H = \frac{V^2 (\sin. a)^2}{2g} = \frac{500^2 \times .707^2}{64.32} = 1943 \text{ ft.}$
11	$U = V \sin. a - gT$

FIG. 6. FORMULAE FOR ANGULAR PROJECTION.

degrees, as shown in Fig. 4. The value for  $U$  at the highest point in the trajectory will be:—

$$V \sin. (a) - gT = 500 \times .707 - 32.16 \times 10.95 = 1.4 \text{ feet.}$$

This calculation should figure out even, but owing to the impossibility of obtaining the exact time, a slight variation is shown. However, it is clear that the shell is travelling at its slowest speed when at its highest altitude, having lost all vertical velocity, and retaining only the horizontal velocity  $V_1$ .

#### Examples Worked Out.

A shell having a muzzle velocity of 1,800 feet per second is discharged from a gun having an elevation of 45 degrees; what is the range and total time of flight?

The total time of flight will be found by dividing the product of twice the velocity and sine of the angle by the force of gravity, or by formula (7),

$$2V \sin. (a) = \frac{2 \times 1800 \times .707}{32.16} = 79.1 \text{ sec.}$$

By formula (8), the range will be the velocity multiplied by the cosine of the angle times the duration of flight, or  $R = V \cos. (a) \times T_1 = 19.04 \text{ miles.}$

Suppose, however, the time of flight was not known and it was required to find the range of a gun elevated to an angle of 30 degrees with the horizontal and a muzzle velocity of 1,500 feet per second, it could be found from formula (9), where

discharge, what is the initial velocity?

$$\text{From formula (7), } T = \frac{2V \sin. (a)}{g}$$

$$\text{therefore, } V = \frac{T}{2 \sin. (a) \div g} = \frac{22}{2 \times .57358 \div 32.16} = 617 \text{ feet per sec.}$$

#### MODERN STEEL PLANT IN INDIA.

A RECENT issue of the Ironmonger contains some interesting information relative to the Tata Iron & Steel Co. of Sakehi, India, of which we reproduce the following more or less essential notes and operation data. The blast furnace plant consists of two furnaces 77 ft. by 19 ft. with 12 ft. 6 in. hearth, equipped with up-to-date charging and weighing apparatus and four Cowper-Kennedy stoves. The first pig iron was made in December, 1911, all the staff being Americans. The estimated capacity of the furnaces is 160,000 tons per year, and during 1914 the monthly output averaged, roughly, 14,000 tons per month.

Analyses of the coke used are by no means ideal, since they reveal an ash content ranging from 20.94 to 23.74 with moisture 5.52 to 10.22. The sulphur is not excessive, ranging from 0.59 to 0.74, whilst the phosphorus in

the ash runs from 0.85 to 1.08 per cent. The approximate cost of the coke during the first six months of 1914 was \$2.50 per ton, and the consumption of coke per ton of iron averaged 21 to 22 cwt. The coke consumption appears low, but this is accounted for by the exceptionally high iron content of the ore. The Gurmasini ore contains about 61 per cent. iron and about .090 per cent. phosphorus, whilst the Chanda ore contains about 68 per cent. iron with .035 phosphorus. The Gurmasini ore is mostly used, being conveniently situated for the works, and the average cost of this ore delivered at the blast furnace bins was 50 cents per ton. Coking coal is obtained at an approximate cost of one dollar per ton. A good grade of manganese ore is also available, the approximate manganese content being 48 per cent. Perhaps the most interesting figure in connection with the blast furnaces in the regularity and excellence of the pig-iron analyses. The approximate average for the six months for each furnace is as follows:—

	Manganese	Silicon	Sulphur	Phosphorus
A Furnace	1.90	0.95	0.025	0.35
B Furnace	1.50	2.5	0.025	0.35

The pig iron was produced at an approximate works cost of \$6.50 per ton, and the selling price averaged approximately \$14.50 per ton. In regard to coke ovens, the original plant consisted of 180 Coppee non-by-product ovens, supplemented later by a number of Beehive ovens. Recently, however, a battery of Kopper by-product ovens has been installed.

#### Open Hearth Furnaces

The steel works comprises four 50-ton open hearth furnaces, each having an independent plant of four producers. The writer states that the steel works gave the most serious trouble owing to the failure of the German staff to operate them successfully. Considerable trouble was experienced owing to the short life of the furnaces due to faulty manipulation, and also arising from the irregular analysis of the steel stated to be due to the use of coke dust in recarburising. It is very gratifying to read that the steel making was put on a proper basis when, at the request of the Company, Professor A. MacWilliam was allowed by the Government to place his metallurgical knowledge and experience at the Company's service.

The cost of bricks was one of the most serious items, and experiments were being made with local bricks. The output of steel ingots early in 1914 was between 8,000 and 9,000 tons per month, at a works cost of approximately \$15.75 per ton. Two more furnaces have re-

cently been constructed, and a greatly increased output should result. The ingots are reheated in soaking pits, and are first rolled into blooms in a 36-in. pinioned reversing blooming mill. After cogging, the ingot is brought back and cut to length, and then charged into reheating furnaces. When rolling 90-lb. rails and other large sections it is possible to roll direct without reheating. The 28-in. finishing mill consisted of three sets of rolls, the first set having a balanced top roll, which was very useful when rolling joists and channels.

In regard to the testing of the steel, the works possess a well-equipped laboratory with the usual testing plant. All structural sections are required to pass the British standard specification, whilst rails and fish plates have to pass the Indian States Railway specification. The inspection is carried out by Professor MacWilliam. A table of analyses taken from representative heats gives an idea

18 IN. WHITEHEAD TORPEDO EXHIBITED AT CANADIAN NATIONAL EXHIBITION.

of the excellent quality of the finished product. An average analysis for 12 in. by 6 in. blooms showed the following:—

Carbon	0.29
Manganese	0.53
Sulphur	0.025
Phosphorus	0.024

The tensile strength is 30.06 tons per square inch, with 26.56 per cent. elongation in 8 inches. The approximate average selling price at the works during the first six months of 1914 for rails and structural sections was \$31.75 per ton, the principal markets being India and Japan.

From the foregoing it will be seen that the works of the Tata Iron & Steel Co. have developed on very sound lines, and there is no doubt that the wonderful resources at the disposal of the Company will render the developments of steel making at Sakehi an important feature in the metallurgical future of India.

#### ENEMY PRODUCTS EXHIBITION

A collection of 8,000 samples of enemy industry, collected in 70 different world markets, will be put on exhibit in Montreal towards the end of

this month. The samples will arrive in Canada on September 20, and after some ten days of arrangement, will be exhibited in Montreal. Only two cities in Canada are to be so favored, Toronto being the other, and it is the hope of the Trade and Commerce Department that manufacturers will avail themselves of the privilege which they will be accorded through the courtesy of the British Board of Trade.

The exhibit was secured for Canada through the immediate offices of Sir George Foster, during his recent visit to the Old Country. It comprises, as stated, over 8,000 articles, the products of German and Austrian industry, which were collected by the Commercial Intelligence Branch of the British Board of Trade, with the object of capturing enemy trade. Wherever shown in Great Britain there has been excited great interest on the part of manufacturers. The idea of bringing the exhibit

here is to ascertain whether Canadian manufacturers are making, or can make, articles of the kind shown, either for foreign or home markets. It is desired to assist them to capture as large a share of enemy trade as possible. In most cases the prices at which the various articles have been sold by German or Austrian merchants are attached.

It was possible to secure the exhibit for Canada for only a limited time, and for this reason it was decided to exhibit it only at Montreal and Toronto, as the largest and most convenient manufacturing centres. It will be on view two weeks in each city. Mr. Kershaw, of the Commercial Intelligence Branch of the British Board of Trade, will accompany the exhibit, and Watson Griffin, Acting Commissioner of Commerce, will have charge of arrangements in Canada. Mr. Griffin will secure suitable accommodation for the exhibit, from 7,000 to 10,000 square feet of floor space being required.

While this will be only a temporary exhibit, arrangements are under way by the Trade and Commerce Department for the establishment of a permanent sample museum at Ottawa. Instruc-

# Evolving Standard Cutting Tools After a Definite Plan--I.

## "Herbert's Monthly Review"

This series of articles dealing with the practical side of the subject of cutting tools may be said to be supplemental to what appeared in our issues of July 20 and 27; cutting tools from the theoretical and analytical viewpoint were then discussed. As efficiency in the machine shop depends largely on the character of the tools used, it is believed to be easily worth while for those concerned to not only sift this tool question to its fundamentals, but for each individual shop to establish a standard tool scheme to suit its own special conditions.

**A**N adequate supply means that no machine need ever be kept standing for want of a cutting tool any longer than is necessary to obtain one from the stores. Efficient cutting tools mean that for every operation on every machine there is a tool available that will give the desired result with the least expenditure of power, in the shortest possible time, and with the maximum of durability. Cheaply made and easily maintained means that the adopted system of tool making must be itself efficient.

### Lumsden System of Tool Making

The following remarks, it may be asserted at the outset, are based on the Lumsden system of tool making and upon the chart which is furnished with every Lumsden oscillating tool grinder.

The Lumsden chart has been compiled by men who for many years have given their whole time to the intimate study of tools; it is based on the results of countless experiments and a wide experience gained in shops of all descriptions, both in the British Isles and on the Continent. A reproduction of this chart is given in Fig. 1. It is not presumed that the 25 tools shown in this chart cover every requirement of every shop, but it will serve very well as the basis of a set of standard tools for any average shop. Each one of these 25 tools will be dealt with separately. Reasons will be given for its existence on the chart, the work for which it is suited will be specified, also the variations it can assume without destroying its individuality. In addition, full detailed instructions will be given for manufacture and maintenance.

### The Lumsden Grinder

It is not the purpose of this article to give a catalogue description of the Lumsden oscillating tool grinder, but it is necessary to give a brief summary of its features and the method of operating it. Briefly, the machine provides a means by which the entire nose of any shaped tool can be presented with ease to the flat face of an oscillating cup wheel. It is absolutely necessary for either the tool being ground or the wheel on which it is ground to be reciprocated across the face of the other; if not, the wheel will rapidly glaze and refuse to cut. In the Lumsden oscillator the reciprocatory movement is done by power instead of muscular effort. All the adjustments of the tool and the wheel are easily made from the working position, and the operator can at all times see what is happening without stopping for inspection.

Thus, the first elements of an efficient tool making system are assured, viz., easy operation, easy control, with the minimum of effort on the part of the operator. For all tools with flat faces no attachment, template or former is required, all the adjustments necessary being obtained in the universal tool holder. For those tools that have hollow curved top faces a simple and easily understood attachment is furnished. This is secured in the tool holder of the machine, while the tool is reciprocated across the corner of the grinding wheel, the combination of angular positions of tool and holder giving any desired amount of curvature.

### The Tool Holder

The tool to be shaped is gripped in a simple chuck, which can be rotated through a complete circle on its own axis. The barrel which contains the chuck is carried in two trunnion bearings, so that the tool can be swung through an arc of about 10 degrees up or down. The trunnions have endwise adjustment in their bearings for use when grinding radius tools in which the centre of the radius does not coincide with the centre of the spindle. The whole tool holder can rotate on a vertical axis, enabling any side or the end of the tool to be presented to the wheel at any predetermined angle. An inspection of the line drawing of the tool holder in Fig. 1

will reveal the universality of these movements.

### The Lumsden Tool Chart

It is desirable that the instructions given in any tool grinding chart should be not only intelligible, but also incapable of wrong construction by the most inexperienced operator. For this reason the Lumsden Chart gives the settings of the tool only; there are no alternatives, so that if the chart is followed the correct angles are given to the tool. In other words, the chart tells the operator what to do, which from his point of view is what he most wants to know.

The actual angles reproduced on the tool are those given in the chart. The one point where they appear to differ is in the designation of the angles given to the front of a tool; but even in this case the chart angles are the same as those actually given to the tool, if measured from the side instead of the front of the tool.

The naming of tool angles, such as rake, top angle, side slope, front slope, clearance, and so on, is liable to misinterpretation, and has been abolished in the present Lumsden Chart. Instead, each tool is sketched, and the tool faces numbered to correspond with the sequence of the grinding operations. Thus, confusion is entirely eliminated, and the chart can be easily read, easily understood, and easily interpreted on the machine.

There are three angular adjustments on the Lumsden Oscillator, each graduated in degrees. These are designated as the turntable, the trunnion and the tool holder respectively. The positions of all three are separately specified for each tool face to be ground. The turntable graduations read so many degrees "back" or "fore" from the zero position. The trunnion graduations read so many degrees "up" or "down," thus indicating the actual movement of the tool nose from the horizontal.

The tool holder has four arrow marks labelled respectively A, B, C, and D. The barrel in which it rotates is graduated so many degrees "left" or "right" of the zero. The four marks, A, B, C, and D, correspond to the four sides of the tool; when arrow mark A is covered by the graduations, the top face of the tool is uppermost, provided the base is flat on the base of the tool chuck. The marks B and D then correspond to the two side flanks, while C corresponds to the base, on which no grinding is done.

### Curved Top Faces

The advantages of the hollow curved top face were set out in the previous articles, so it is not necessary to reiterate them here. A curved top face can be ground by the Lumsden Oscillator almost as easily as a flat face. The profile of the tool, that is the shape seen from

the top, is first ground without the use of the attachment. When a batch of similar tools have been thus "profiled" they can be finished with curved top faces by means of the curved face attachment furnished with each machine in very little more time than would be required if they were ground with flat top faces. The degree of curvature given to the tool, and consequently the rake at the cutting edge, can be varied by commencing the grinding nearer to or farther from the cutting edge. This will be readily comprehended by referring to Fig. 2.

This method of increasing the keenness of the cutting edge, however, may not be desirable owing to the resulting length of the ground face from the tool nose. Another method is open in such a case, and that is swivelling the attachment slide more towards a vertical position, a method which causes the tool to be reciprocated more on the corner of the wheel.

FIG. 2. DIAGRAM SHOWING EFFECT OF COMMENCING GRINDING OF A CURVED TOP FACE AT DIFFERENT DISTANCES FROM THE CUTTING EDGE.

When using the attachment, the trunnion setting must be at zero, that is, the barrel in which the attachment is gripped must be horizontal. For right-hand tools the position of the turntable has been found by experiment to give the best results when set at  $42\frac{1}{2}$  degrees back, so that the front and the side of the wheel make equal angles with the tool. When grinding left-hand tools, owing to the position of the tool nose relative to the movements of the wheel, the turntable should be set at 25 degrees back. These two settings need never be altered for any shape of tool.

The tool is secured in the holder of the attachment in such a position that the cutting edge is parallel with the slide. A tool having a curved cutting edge is set so that a tangent with the average centre of the cutting edge is similarly parallel to the slide. The slide is set to 15 or 20 degrees (see chart, Fig. 1) from the vertical, and clamped in that position. Grinding takes place without

the oscillating motion of the wheel. The wheel is then advanced and adjusted sideways until it just touches the tool at a point distant from the cutting edge, the amount varying with the size of the tool and the degree of curvature required. This amount is decided by the ultimate position of the deepest part of the grinding. For a small tool, say,  $\frac{3}{4}$  in. x  $\frac{1}{2}$  in., it can be about  $\frac{3}{8}$  in.; for a large tool, say, 3 in. x 2 in., about 2 in. will be necessary. A good rule to follow is to make the length of the top face equal to the width of the tool. In any case, it will soon be seen as grinding proceeds whether the desired effect is obtained or not, and correction made accordingly.

The tool is next passed up and down across the corner of the wheel by means of the lever at the top of the slide. While grinding proceeds, the wheel should be fed alternately forward and sideways by means of the two hand wheels which control these movements. Grinding continues until the cutting edge is reached. It should always be the endeavor of the man in charge to have tools ground in batches; this decreases the cost of making the various settings, and encourages greater efficiency in the operator.

### Grinding Radii

The swivelling movement of the turntable on its vertical axis is extremely handy for grinding radius and round-nosed tools. To do this, the tool is set so that the centre of the desired radius is exactly over the axis of the turntable; then, with the wheel stationary or oscillating but slightly, the turntable is rotated back and forth until the desired curve merges into the sides and end of the tool.

To facilitate setting, a radius gauge is provided, the procedure being as follows: First grind the end of the tool with the necessary clearance, then the side of the tool, also with clearance. Run the wheel back and reset the tool in the chuck, using the radius gauge to determine the forward position of the tool nose. Next adjust the barrel of the chuck sideways in the trunnion bearings, using the graduated scale to bring the centre of the desired radius over the axis of the turntable. Set the turntable to 90 degrees back, bring the wheel up till it just touches the tool, and set the stop which limits the forward motion of the wheel. Run the wheel back again, then commence grinding, swivelling the turntable and feeding the wheel forward till the stop is reached, when it will be found that the radius is completed.

### Standard Tools

In deciding on the set of tools incorporated on the Lumsden Chart, the authors have had in mind the elimination of forging as far as possible. Sixteen out of the 25 tools shown can be roughed to shape from a piece of

straight bar. Four of the remaining nine only need bending, a very simple operation. The two tools for finishing fillets, Nos. 24 and 25, only need forging when the radii are larger than, say, half the tool width. The 25 tools shown cover the majority of the requirements of the average shop, as will be seen later when their purposes are described.

Tools numbered 1 to 14 can be ground with a hollow curved top face, and it is strongly recommended that they should be so ground, for the reasons previously advanced. The requisite settings for grinding these tools to such a shape that they will be suitable for machining mild and the lower carbon steels are given on the left of the chart. These settings replace those otherwise used for grinding the top face flat, and do not affect the shaping of the tool profile.

All the other settings given have been chosen, as the result of a very wide experience, to give a tool suitable for 30-ton steel, with the exception of the last four, which are intended for special purposes. The resulting rake of the top face can, of course, be varied to suit the material to be achieved, the keenness being increased for softer materials and decreased for harder materials.

#### Tool No. 1

No. 1 is a round-nosed tool intended mainly for planing and shaping. The top face slopes away from the point, there being no side cutting angle at all; it also has clearance on both sides, so that it can be used for feeding in either direction. It is in addition a useful tool for necking the journals of axles and shafts. The roundness of the nose can be varied to suit different conditions. For instance, for turning a slender camshaft between the cams, the point should be made fairly slender, say,  $\frac{1}{8}$  in. radius, whereas when turning railway carriage axles, where chatter is not likely to occur, the nose can be much blunter, say,  $\frac{1}{4}$  in. up to  $\frac{1}{2}$  in. radius, depending on the size of the tool. This tool is preferably made from steel of a depth about one and a half times its width.

#### Grinding Instructions Tool No. 1

Set the end of the tool blank by means of the radius gauge to give a radius equal to the width of the tool section. Adjust the trunnion to the right an amount also equal to the width of the tool.

The two sides of the tool should be ground complete in two distinct operations. In grinding face 1, the tool holder is rotated till the base of the tool is uppermost. Set the turntable to 10 degrees "back," and grind the side of the tool away for a length equal to the tool width; then, without altering any adjustment and while the tool is still in

contact with the wheel, unclamp the turntable and slowly sweep it round to the left till the tool leaves the wheel. Repeat this operation on face 2 without removing the tool from the tool holder; this time, however, the base of the tool will be downwards.

Note particularly that, to obtain the correct clearance on the two sides, the trunnion is set to 26 degrees "down" and the tool holder to C.3 degrees "right" for face 1. Both these settings are reversed for face 2, that is, the trunnion is set to 6 degrees "up" and

The top face is next ground to give the desired rake—in the Chart this is given as 15 degrees, as any greater keenness would cut too deep into the tool. It is, therefore, strongly recommended that this tool be always ground with a hollow curved top face, as a keener rake is obtained without weakening the tool. For hard materials, such as cast iron, however, a flat top face with 10 degrees rake is better, the settings for operation 3 being:

Turntable. Trunnion. Toolholder.

the tool holder to A.3 degrees "left." The point should be just touched up, giving 6 degrees of clearance, the setting being (though not given in the chart):

Turntable. Trunnion. Toolholder.  
90 back. 6 up. A zero.

The point can be rounded off later by hand on a plain grinder, although on large tools, which require a large radius on the point, it can be done in the oscillating grinder by setting for the desired radius.

#### RAILWAY EMPLOYEES PROTECTION

ANOTHER step forward in the matter of safety for railway employees in Canada is embodied in an order just issued by the Railway Commission regarding handrails on locomotives.

It is ordered that all railways subject to the jurisdiction of the Board shall equip all locomotives of 100,000 pounds or over with handrails on the side of the cabs above the windows, running the whole length of the cab, and that the tenders of all such locomotives shall

be equipped with railings on both sides on the top of the coping.

The rails on the tenders are to run the full length of the fuel storage. Foot-rests in the cabs are also ordered. This applies to all locomotives of the class described except those used in international traffic and merely passing through Canada.

The order is the outcome of a hearing a year ago when representatives of the Brotherhood of Locomotive Engineers and the Brotherhood of Locomotive Firemen and Enginemen asked for such protection. Representatives of the Canadian railroads were also present.

### TO ENCOURAGE BUILDING OF SHIPS

THE Dominion Government has under consideration a plan for the encouragement of shipbuilding in Canada by an extension of the present system of State aid toward the construction of dry-docks.

### NEW "DAY LETTER" SERVICES

THERE was inaugurated on August 28, by the C. P. R. Telegraphs Department a new day letter service which in its essential features makes a rate of transmission of messages available at a considerable reduction when compared with the previously existing commercial rush telegram.

It is believed that many of those who send telegrams would be quite satisfied if these arrived on the same day. Again, a proportion of the cost of the rush telegram is due to the cost of speedy delivery. The day letter of fifty words will be rated at one and a half times the cost of a regular rush message of ten words, and will still bring an answer the same day, which is as quick as many people desire.

There are sixteen hundred C.P.R. telegraph offices throughout Canada, at each of which the new service is in force, so that this will be a Dominion-wide service stretching from Louisburg, N.S. to Victoria, B.C. Messages will be taken in either French or English, code words not being permissible.

an enquiry through the Colonial Office on behalf of the Australian Government as to whether Canadian firms desire to export goods direct to the Pacific Islands, being former German colonies which have been captured and are being occupied by Australia. The Australian Government states that any importation of goods into these Islands from Canada is at present made only through the Commonwealth. The Pacific Islands were taken from Germany in the first two months of the war by the Australians and Japanese and comprise groups of small islands stretching across the Pacific from the Philippines to the French Marquesas. They are known as Kaiser Wilhelm's Land, Bismark Archipelago and the Caroline, Pelew, Marianne and Marshall Islands.

### CANADIAN VESSEL REGISTRY

A DECLINE in the number of vessels in Canadian registry is shown by the figures for last year, which have been compiled at the Marine and Fisheries Department. The total number of ves-

ONE OF THE NUMEROUS C.N.E. AVENUES LINED WITH EXHIBITS FROM CANADA'S MANY ENGINEERING ESTABLISHMENTS.

The desirability of reviving Canadian shipbuilding by some form of Federal aid was discussed at the last session of Parliament, and a sub-committee of the Cabinet was subsequently formed to study the situation. It is learned that the most likely course to be adopted and that on which the committee is at present bending its energies will not provide for direct State aid for shipbuilding, but will attain the same end by a relaxation of the conditions under which dry-dock subsidies are now granted. Two drydocks are already under way in Halifax and St. John but conditions have arisen which have made it impossible for the full benefit of the subsidy allowance to be secured for these enterprises. These will be made less stringent, and it is hoped in this way to take the first step towards encouraging shipbuilding in the Dominion.

It is also announced that there will be accepted and forwarded between all points on lines over which the G. T. P. Telegraph Co. operates i.e., Grand Trunk Pacific, Transcontinental, and Canada Atlantic Railways, day lettergrams, which will be treated as a deferred service subordinate to the priority of the transmission and delivery of regular telegrams, and charge being one and one-half times the ten word day message rate per 50 words or less, and one-fifth the initial rate for each additional ten words or less. Day lettergrams may be written in English or French. Code words are not permitted.

### CANADIAN GOODS FOR PACIFIC ISLES.

THE Canadian High Commissioner's Office, London, England, has received

sels so registered was 8,757, of which 4,132 were steamers. The total net tonnage was 929,312. The decline is not so great as would appear from a comparison of the figures with those of the preceding year, owing to the fact that a revision of the list resulted in the elimination of the names of a number of vessels which had been carried, but were no longer in commission. The number of new vessels constructed was less. It totalled 246 last year, of 18,832 tons, as compared with 329 the previous year of 43,000 tons. Although the number of ships decreased there was an increase in the number of sailors serving on board them. The figures were 45,461 as compared with about 42,000 the year before.

The Hudson Bay Railway offices have been removed from Winnipeg to The Pas, Man.

## RECLAIMING RUSSIAN THREE-INCH SHRAPNEL FUSE BODIES

By H. M.

IT is a well-known fact that the inspections for the Russian fuse are most rigid. Many manufacturers, not realizing that this high degree of accuracy could not be consistently attained by

FIG. 1. OUTLINE DRAWING OF FUSE BODY.

using makeshift tools, found much of the work was rejected in the early stages of their manufacture owing to the manufacture of the fuse not yet having reached a commercial basis where a high degree of accuracy could be obtained. This being the case many producers are now turning their attention to the reclaiming of some of the rejected work. Of course, much of the work which has been rejected either cannot be saved, or the parts being so simple it is not worth the trouble. However, one of the most expensive parts of the fuse is the body which is shown in Fig. 1, this in the case of the three inch fuse being made from an aluminum composition casting which is compressed and is machined all over.

A large number of these bodies having been rejected owing to the shoulder A being too short, they were picked out and if the diameter B had sufficient stock to permit, this diameter was rolled with a tool such as is shown in Fig.

FIG. 2. METHOD OF LENGTHENING SHOULDER "A," FIG. 1.

2. This compressed the metal lengthwise thereby lengthening the shoulder A. The tool Fig. 2, consists merely of

a roll A mounted on a stud B in a suitable holder C which is sufficiently strong to resist the pressure of rolling the aluminum over. During this operation the work is held on the large diameter in chuck jaws D and is supported by the back rest E.

Another trouble experienced was from the pitch diameter C, Fig. 1 being small, this error was always very slight and as the tolerance on the outside diameter of the thread was greater than that allowed on the pitch diameter an attempt was made to reclaim bodies rejected from this cause by rolling the thread with the tool Fig. 3. This tool was made with the idea of jamming the top of the thread thereby causing the metal to be squeezed outward at the pitch diameter.

This tool is similar in construction to that illustrated by Fig. 2, with the ex-

FIG. 3. SHOWING METHOD OF ROLLING THREAD TO INCREASE PITCH DIAMETER.

ception that it was made straight instead of off-set, an off-set tool not being considered necessary to prevent interference with the chuck because the work at this setting was held on the diameter A, Fig. 3, with a back rest at B, and a revolving centre in the holder C. From this application of rolling very good results were obtained and many fuse bodies were thus saved.

To save bodies which had the diameter E bored out too large, it was found that there were two chances to save them, namely, if the diameter D had sufficient stock to permit of rolling with the tool Fig. 4, the top diameter was squeezed thereby causing the metal to be compressed sufficiently to allow of boring the diameter E to the correct size. When this method was resorted to, it was usually found necessary to trim up the face X, at the bevel side although the roll shown in Fig. 4, has a shoulder X which supports this side to

a certain extent while rolling. The manner of holding the work for this operation is clearly shown by the illustration and consists of, holding the work in chuck with a back rest of the single jaw type backing up the work at the bevel surface Z, while a revolving pad Y helps to take the end thrust.

FIG. 4. ARRANGEMENT OF TOOLS USED FOR ROLLING OUTSIDE DIAMETER.

The other chance of reclaiming the bodies when the diameter E is large is preferable to the one just mentioned. This is to apply a roll on the surface F, provided the depth G is long enough to permit this. The roll for accomplishing this is shown in Fig. 5, where the work is gripped in chuck jaws A, while the roll B, held in holder C, is forced against F thus rolling the metal in and causing the diameter E to contract.

It will be obvious from the foregoing descriptions that the work of reclaiming is a matter which calls for considerable good judgment on the part of the man who is doing it, and while every attempt will not result in success it has been found that many of the bodies can be saved from the scrap heap by intelligent effort and this saving is sufficient to make the expense of the rolling tools a very good investment.

FIG. 5. SECOND METHOD OF INCREASING DIAMETER "E," FIG. 1.

as in most cases the cause for rejecting the bodies was found to be but a very slight error in the examples noted.

## GRINDING BRASS VALVES

By D. A. Hampson.

WITH the automobile came the process of valve grinding on such a scale that it has been brought home to most mechanics who, if told to grind in any kind of a valve, would straightway start the work with emery and oil or one of the various compounds of these. There is, however, a class of valve grinding met with in shops of supply manufactures and in certain branches of repair work that is quite different and little known outside of these lines. In this class are pet and stop cocks, valves used on bar and restaurant fixtures, shut off cocks for house water systems, and valves used in bottle filling work in various kinds of food production and packing.

All of these "valves" have a cylindrical core turned to a taper of approxi-

FIG. 1. PATTERN TO BE MOULDED.

mately one inch to the foot and fitting in a body reamed to the same taper. The core is held to its seat by a "D" washer and nut at the small end. The material is cast brass of the best grade.

In the manufacture of these valves the taper of the two parts is made to correspond exactly, thereby reducing the amount of grinding; in repair work, circumstances may compel all the re-fitting to be done by hand grinding or grinding after awkward shaped pieces have been machined, perhaps none too well because of their shape.

Grinding is imperative—a perfect fit cannot be secured in any other way—for liquids such as gasoline, the familiar lead pencil mark and other visual tests, are not good enough, and the valves are tested by suction. In manufacturing this is done by applying the valve to a quick acting connection on the shop vacuum system—if the valve holds its weight, it is ready for any service—and

a corresponding test for heavier valves. On a repair job the rather unsanitary method of testing is to put one of the connection ends in the mouth, close the

FIG. 2. ILLUSTRATING FORMER METHOD OF MOULDING PATTERN.

lips tightly around it, and with a deep inward breath place the tongue over the opening. If the tongue is held fast, the valve is sure to be tight — tight enough for gasoline. Another less positive way is to oil valve and core and then blow in the connection looking for bubbles at the joint as an indication of a leak.

Sand is by far the best grinding medium for brass valves; emery or corundum should be used only when no sand is obtainable, for it is well nigh impossible for even a skilled grinder to keep from scoring the surfaces—something impossible with sand of the right kind, though the greenest boy in the shop does the work. White sands are used for valve grinding—sea sands or certain sands produced by glacial action—dry, sharp, and free from loam and vegetable matter. In general, any sand which is good for locomotive work will do for valve grinding.

The valve grinder oils the core, rolls it in sand and thrusts it, coated, into the valve. The actual work is as with any valve—turning the core through a small arc, shifting to another position and repeating with additions of oil as the work gets dry. Any of the common shop oils will do the work. The parts are cleaned in a pail of kerosene and

FIG. 3. PATTERN MOULDED ON FLOOR BOARD READY FOR TURNING OVER.

the experienced grinder does not remove the core when the test shows a perfect seat, he simply washes the sand out

through the ports. The sand is better used sifted, but if not, the larger particles or pebbles are shaken off after the oiled core is rolled in it.

## COST-CUTTING ON A TURN-TABLE COLUMN

By J. H. Eastham.

THE demand for quick delivery along with high quality of product was very marked during the revival of trade after the South African war, extensive orders being placed with British firms specializing in railroad equipment, such as cranes, turntables, etc. Pressure from purchasers caused many changes to be made in former methods of manufacture, the turntable column described herewith being one in-

FIG. 4. CIRCULAR PLATE BETWEEN DRAG AND CONICAL FLASK.

stance where the time was not only reduced, but a better job done at the same time.
